2. In industrially advanced countries, the share of GDP typically spent on R & D varies between 1.5 and 3.0%, compared to 0.5 and 1.5% in the newly industrializing countries, and less than 0.5% in the rest. The share of national R & D funded and performed by business firms tends to positively correlate with increasing GDP per head and is widely recognized as an indicator of the degree of industrialization and modernization pursued by the industrially latecomer countries.
3. More than 60% of all business-funded R & D is typically performed in the chemical-, biotechnology-, electrical-, electronic-, and automobile-related industries. Currently, the largest individual corporate R & D spenders are the world's leading automobile, biochemical, electrical, and ICT firms.

The Economic Determinants and Impact of R & D Activities

The improved quality of R & D statistics has enabled economists and other analysts to more deeply understand both the determinants and the economic impacts of R & D activities, at the country, industrial, and firm levels. A number of analysts have been able to show that, among the industrially advanced countries, differences in the levels and rates of growth of national R & D activities have a significant influence on differences in national performance in exports and productivity (Fagerberg, 1987; Furman et al., 2002). In the industrially latecomer countries such as the East Asian Tigers, studies of R & D conducted by public research institutions, such as ITRI for Taiwan or KIET for Korea, made it clear that they had indeed been the architects of the technological catch-up strategies and had been responsible for acquiring the technologies that were then rapidly diffused throughout the business sector (Hu and Mathews, 2005). This was a feature not observable in studies of industrially advanced countries, however.

At the industry level, considerable attention has been given to the effects of firm size and industrial structure on R & D activities. Given the dependence of specialization on scale, the proportion of firms performing R & D increases with firm size. For example, by using USPTO patent data, Hu (2012) demonstrated that R & D activity and degrees of specialization vary with firm size and industrial structure, in the development of the TFT-LCD (thin-film transistor-liquid crystal displays) industries in Japan, Korea, and Taiwan. Specifically, advanced Japanese firms formed inter-*keiretsu* collaborations to increase both technological scale and efficiency (i.e., both R & D scale and intensity) while protecting itself from the risks of a technological and capital-intensive industry. To the extent that technological opportunity was available, Korean conglomerate latecomers increased their *scale* of technology specialization (i.e., R & D scale) to improve their market performance, while Taiwanese small to

medium-sized latecomer firms pursued *efficiency* of technology specialization (i.e., R & D intensity) by utilizing their limited R & D resources. This is compelling evidence that variations between industries in both the concentration and intensity of R & D are determined, jointly, by a third factor, which concerns the differences in technological opportunities available between industries (Levin et al., 1985).

Less progress has been made so far in measuring the effects of differences in R & D expenditures on company performance. This is partly because comprehensive and comparable R & D data at the company level are only now slowly becoming available. Also, the intangible effect of R & D spillovers is often induced and moderated by external factors such as industry-level technological opportunity and institutional design at the country level (Coe et al., 1997, 2009). It is also because of the difficulty in defining a proper measure of corporate performance. Those used include the R & D production function, stock market evaluation, and long-term growth (Patel, 2000).

Limitations of R & D Statistics

As shown above, R & D activities can be a useful proxy measure for innovation, but these have their limitations. The most often mentioned of which is that they measure inputs and not outputs. Equally, if not more, important are the following:

1. In large firms, R & D statistics do not measure the often considerable expenditures on outsourced or complementary activities in production and marketing that are necessary to transform the outputs of R & D into commercially successful innovations.
2. In small firms, they do not measure innovative activities conducted by part-time, external manpower, which are particularly important in the machinery and software sectors.
3. For service sectors such as finance and distribution, R & D activities are very imperfect proxies, because a growing volume of innovative activities in software are now being performed in firms. In such sectors, however, quantitative outputs performed in the market are largely mediated by qualitative indicators such as qualified manpower and management skills.

To improve the limitations of traditional R & D statistics, indicators of knowledge-generation and innovative activities have been developed. The most applicable of these have been counts of patents and scientific papers, as well as their citations, technology licensing and royalty revenues, and the number of new and innovative products and services (Hu et al., 2014). By using patent information, the impact of R & D activity can, to some extent, be evaluated and measured, by examining the patenting activity of each organization in comparison with its competitors and collaborators. We addressed this as follows.

Patent Information versus R & D Activities

In knowledge-intensive economies, intellectual property rights (and especially patents) have become valuable assets for R & D activities and decisive strategic factors. They protect R & D achievements, raising research performance, creating profit and maintaining competitive advantages for countries, industries, and firms. In particular, the patent document is considered one of the major indicators of cutting-edge technology, and holds great commercial value. The WIPO (World Intellectual Property Organization) reported that over 90% of R & D achievements were disclosed in patent gazettes, 80% of these not being revealed in academic journals or the technical literature. Therefore, one of the clearest indicators of R & D performance is the rate of take-up of patents issued by the patent offices, although the precise rate of technological innovation is not measurable. Based on this, different indicators are being developed and used to predict the value of a particular patent, or an organization's R & D strength.

The standard patent indicators most utilized are patent number and the growth rate of patents in a given organization. Since patents can vary enormously in their importance or value, simple patent counts are unlikely to capture the full force of the innovative output of the sector (see, for example, Jaffe and Trajtenberg, 2002). Thus, the alternative is patent citation rate, which is recognized as a proxy reflecting the impact and depth of R & D activity. While research has established that highly cited patents represent economically and technically important inventions (e.g., Griliches, 1990), we list five of the most popular patent citation indicators, invented by the ipIQ, to evaluate R & D activities. (ipIQ (formerly CHI Research) is one of the foremost intellectual property consultants, providing technology-oriented services, including IP-related industry surveys and reports to firms contemplating acquisitions. The company has formulated various measures of patenting quality, which can be deployed through own calculations.)

1. Forward citation rate – a count of the citations received by an organization's patents from subsequent patents. This helps to evaluate the technological impact of patents. High citation counts are often associated with important inventions, ones that are fundamental to future inventions and that may have more competitive advantages in a given technological field.
2. Backward citation rate – a count of the citations to prior patents made reference by an organization's patents. This helps to trace the source of innovation/knowledge as well as the developmental trajectory of innovation capability in the organization.
3. Current Impact Index – represents the number of times in which an organization's previous 5 years of patents are cited in the current year; this shows how frequently the organization's R & D outcomes were used as foundations for other inventions.
4. Technology Cycle Time (TCT) – indicates speed of innovation or how fast the technology is turning over, defined as the median age of the patent cited on the front page of a patent document. The TCT is measured in years. This indicator can measure the pace of technological progress. Shorter cycle times reflect faster substitutions, indicating faster progress; while longer cycle times reflect slower substitutions, indicating slower progress.
5. Science Linkage Indicators – the counts of patent references citing to scientific papers. Increasingly, patents are citing nonpatent documents as prior art, and many of these are

papers in scientific journals. High science linkage thus indicates that a patent is building its technology based on advances in science.

By making use of patent information, decision-makers are thus able to assess their own R & D portfolio in comparison with their competitors within and across the industry/country. Patent analysis enhances the ability to assess the attractiveness of technologies, especially those posing a threat, or new opportunities for the existing business; recognize strategic changes in the competitive environment; identify and assess external sources for knowledge generation (e.g., mergers and acquisitions (M & A) and R & D alliances); assess the status of patent appropriation in new business areas; evaluate important market partners, especially customers and suppliers, to determine whether the firm's R & D strategy is in alignment with that of its major customers and competent suppliers; and improve human resource management pertaining to leading inventors in specific technological fields. In summary, integrated patent information can act as a quick and efficient monitoring system for capturing R & D trends in the firm/industry/country by the timely review and updating of patenting portfolio analysis.

Conclusion: Contemporary Debates in R & D Management

Since the nineteenth century, many of the characteristics and problems of managing corporate R & D have remained until today. Of these, the most important issues are as follows

1. The need to orchestrate and integrate specialized knowledge and skills across disciplines, professions, functions, and divisions.
2. Progressive improvements in fundamental scientific understanding, accompanying the increasing systemic complexity of innovations – a process that will continue with the more widespread application of the techniques emerging from ICTs.
3. The difficulty of making reliable predictions, demonstrations, and measurements about the success or otherwise of specific innovations, especially major ones.

Various types of methodologies and open source/proprietary software (such as the above-mentioned TRIZ, business modeling, and knowledge integration simulations) have been developed to help overcome these problems that affect the journey of products from the stages of R & D to market.

At the same time, new problems and challenges have emerged.

1. With increasing specialization in both the production of knowledge, and of the components of increasingly complex systems, firms are faced with increasingly difficult choices about what products and knowledge to outsource, and what to retain in-house. An important part of the in-house R & D function is now devoted to the coordination of innovative and production activities external to the firm through examination and regular monitoring of patenting activity within the nation and throughout worldwide patent data bases, including the WIPO, Trilateral patent offices (including US Patent and Trademark Office, European Patent Office, and Japan Patent Office), and China's State Intellectual Property Office.
2. While the risks and costs of developing cutting-edge products are rapidly increasing, efforts to secure intellectual property appropriation by means of IP licensing and litigation have reached a critical stage, and now face challenges in the deployment of business/industrial/national strategies. In many instances, especially in the industrially latecomer countries, impositions of high licensing royalties and threats of patent infringement lawsuits become significant barriers to entry, together with transaction costs for business expansion and industrial development in a nation.
3. In addition to the well-established function of supporting foreign production, large firms are performing a growing share of their R & D outside their home country, in order to tap into the increasingly numerous international sources of leading-edge scientific and technical advances, as well as in local markets. This poses new challenges for managers in integrating skills and knowledge over long distances and diverse culture (Niosi, 1999), and for national policy-makers in assessing the location and institutional benefits of public investments and resources allocation. Consequently, a multidisciplined and well-trained workforce has become one of the most valuable assets for companies, industries, and nations as a whole.
4. The evidence has shown that academic research is becoming increasingly linked to commercial R & D activities, wherein academic R & D performance is measured by not only publications but also technology licensing revenues, and transfer and number of start-ups. For some, this is the consequence of an unwelcomed financial and institutional pressure from governments on universities to trade-off their forward-thinking 'basic research' with short-term oriented 'applied research and experiments.' For others, it is the consequence of fundamental changes to the role of universities, now supplying a well-educated workforce for knowledge exploitation. This cultural transition of universities challenges policy-makers in the management of academic research.

This study revisits the often-discussed topic of the conceptualized influence of R & D management at the country, industry, and firm levels. The relationship between R & D activity and market performance in each organization is associated with different resource allocations, which affect and are affected by specialization levels, technological opportunity, industrial-specific concentrations, and country-specific investment and institutional preferences. Patenting information provides specific and reliable indicators for R & D evaluation. Furthermore, the contemporary debates and challenges in R & D management indicate that other non-R & D measures, such as inter- and intraknowledge sharing and integration, linkage between basic research and applied research, strategic business and cross-licensing alliances, and fluid manpower flows are crucial complementary drivers that reduce transaction costs in the commercial processes of R & D activities.

Research and Theory Building in Social Work

Jane F Gilgun, School of Social Work, University of Minnesota, Twin Cities, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Grounded theory and deductive qualitative analysis share an intellectual heritage with social work. Common roots include a focus on lived experiences of research participants, who in social work typically are service users and service providers. They also incorporate other qualities associated with social work, such as understanding persons in context, action orientation, and focus on understanding multiple perspectives through immersion in the field. Research findings, therefore, are useful and usable to practitioners.

Introduction

Grounded theory (GT) and deductive qualitative analysis (DQA) are important ways to do social work research because of their fit with the mission and definitions of social work. Like social work, both focus on human interactions in social environments, multiple meanings and multiple dimensions of human phenomena, immersion in field settings, interpretations grounded in understandings of human experience, and action orientations. Social work's emphasis on social justice springs to life when researchers seek the meanings that research participants attribute to issues that compose their lived experiences. The emphasis of GT and DQA on multiple meanings and perspectives fits not only with human experience in general but also with the worlds of practitioners (Gilgun, 2005a, 2012a,b). Those worlds typically are complicated, untidy, confusing, and often intrusive and traumatizing (O'Sullivan, 2011). The goodness of fit between practice and these two forms of research raises the likelihood that social workers will find the results of GT and DQA research immediately useful.

This article will demonstrate the relevance of GT and DQA to the development of knowledge important to social work practice. Although the focus is on practice, the ideas may be tested for fit with other domains of social work. This article begins with definitions and discussions of social work-specific research and related terms, moves to an overview of the procedures for carrying out these two forms of qualitative research, attempts to clarify confusions over what GT is, and shows the kinds of products that researchers can develop from these two approaches. While there are many ways to develop theory, this article focuses on two, both of which have roots in the Chicago School of Sociology. Social workers made significant contributions to the research methods and methodologies of the Chicago School (Bulmer, 1984; Deegan, 1990; Forte, 2004; Gilgun, 2012a,b; Oliver, 2012). This school flourished in the first part of the twentieth century, and its legacy endures. It is no coincidence that GT and DQA fit assumptions of social work.

Definitions

Terms relevant to this article are social work-specific research, focused research on social work practice, theory, theory building, hypotheses, concepts, conceptual frameworks, evidence, critical realism, deduction, induction, and practice. While there are many definitions for each of them, this article only defines terms as they are used in the present discussion.

There are two broad types of social work research. One is *social work-specific research* and the other is *focused research on social work practice*. The emphasis of published focused research on social work practice is on researcher-defined questions and interpretations; surveys, questionnaires, and other close-ended ways of gathering data; and sophisticated analysis of data that few practitioners and many researchers understand or want to understand. While audiences may have difficulties with the mathematics of this research, it is important research to do because it shows that in specified situations with specified populations certain interventions work. Some call this type of research *empirical*, but there are many definitions of this word, including the idea that any research that is based on data is empirical. Mathematics does not make research empirical. Data are materials that take the form of words and numbers and represent the experiences of research participants.

The following articles exemplify focused research on social work practice: Byrne et al. (2013), Katz and Herskowitz (2012), and Thyer (2001). Many articles published in two US-based publications, *Research on Social Work Practice* and *Social Work Research*, are of this type. Since social work is an intervention-based discipline, establishing a mathematical foundation for its interventions is essential.

Social work-specific research incorporates principles from definitions and missions of social work that are present in codes of ethics and discussions of social work's methodological principles that appear in published articles. These typically focus on the perspectives of participants, the questions become participant defined, and researchers seek to understand multiple perspectives within person–environment interactions. Additionally, this type of research may also be based on researcher immersion into social settings, be explicit about ethics and values such as antioppressive practice and social justice, and be clear regarding the links between general statements about findings and the data on which these are based. This research contributes much to social work's knowledge base, but cannot establish incidence and prevalence, nor can it offer mathematical interpretations. See as examples of the ideas behind this type of research, the codes of ethics of social work in various countries and the work of Dominelli (1996), Forte (2004), Saleebey (2004), and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28086-0

Strier (2007). Articles like these appear regularly in journals such as the *British Journal of Social Work*, *Australian Journal of Social Work*, *Families in Society*, and *Qualitative Social Work*.

In this article, theories are conceptualized as transportable sets of ideas that social workers can apply to particular cases or situations, whether these situations involve individuals, families, groups, communities, nations, policy, or advocacy efforts. Theories illuminate social processes and help observers notice aspects of phenomena that they might otherwise have overlooked. Concepts and their relationship compose theory. Theories are provisional and subject to further testing and modification. Theories typically are based on multiple sources of information, such as research, theory, practitioner expertise, personal experience, experiences of populations of persons whom social work serves, and personal and professional values.

Hypotheses are statements of relationships between concepts. The term is often used interchangeably with *theory* in GT and DQA. In the process of doing the research, hypotheses are called working hypotheses in that they are the ideas with which researchers work as they do the research. Researchers test them for fit and modify them when warranted. The products of a GT or DQA study that seek to develop theory are hypotheses. Typically, researchers discuss the hypotheses, a process often called interpretations, and then they situate the hypotheses and their interpretations within scholarly traditions, showing how the hypotheses fit with, add to, and undermine what is already known.

Concepts are the components of hypotheses and are abstractions from concrete descriptions of processes and other phenomena. Concepts are often sensitizing in that they "suggest directions along which to look" (Blumer, 1986: p. 148) as researchers engage in data collection, analysis, and interpretation. Sensitizing concepts are defined in open-ended ways and are flexible in order to incorporate new meanings as evidence is identified to redefine them. In contrast, definitive concepts have clearly fixed meanings and attributes. Theory-guided research like DQA always uses sensitizing concepts, sometimes as a guide to research and sometimes for the purposes of developing theory.

Conceptual frameworks are a synthesis and integration of existing research and theory relevant to the topic of the research. They are the perspectives with which researchers begin most studies, including DQA studies. Often researchers make statements about their experiences, values, and expectations that are relevant to their focus. In these statements, called reflexivity statements, researchers discuss their personal and professional perspectives and attempt to account for the possible perspectives of research participants, including issues related to power between researchers and research participants (D'Cruz et al., 2007; Gilgun, 2008). These statements typically follow reviews of the literature. Conceptual frameworks are the sources of hypotheses and concepts that researchers use to provide focus and guidance to research. Often researchers show how their reflexivity statements play a part in developing a focus and hypotheses and concepts. The components of theory that researchers use when conducting research are called working hypotheses and working concepts.

Evidence is not raw data, but data that researchers filter through their own worldviews, assumptions, and experiences. This is a critical realist stance that also recognizes that what composes data exists independently of anyone's experience and interpretations of it. Data, as defined earlier, are composed of words and numbers that represent the experiences of research participants including those of researchers. Thus, both DQA and contemporary understandings of GT fit assumptions of critical realism, which is an emerging perspective in social work (Longhofer and Floersch, 2012). See Houston (2001) and Oliver (2012) for further discussion of critical realism in general and in social work in particular.

The term *knowledge* in this article refers to information and understandings that researchers and practitioners develop from their professional practices, from their personal and professional values and personal experiences, and from their understandings of research and theory. Knowledge is information and understandings that researchers and practitioners have used, tested in various situations, and modified to fit new learnings.

Theory building is composed of any number of procedures that lead to the production of theory, where theories are sets of transportable ideas that can be applied to specific situations. Theory building is especially important in social work because of the need to understand complex social situations. Theories and the concepts that compose them can illuminate these situations, even as practitioners are alert for dimensions of situations that theories do not cover and thus seek to individualize interventions.

The word *deduction* has many meanings. For the purposes of this article, deduction refers to processes that involve the use of prior theory, where the concepts and the hypotheses of the theory are the starting points of research. The processes of deduction involve understanding the various connotations of theoretical material and capacities for identifying concrete phenomena such as actions, behaviors, and beliefs as encoded in words and other texts, and as instances of cases that fit the theory and its concepts. A second understanding important to this article refers to, in the words of Dewey (1910), 'complete thinking,' which involves both deduction and induction. Deduction is a process of testing working hypotheses, for the purposes of "confirming, refuting, and modifying" (p. 82) them. Hypotheses are not fixed conclusions, but are open to further testing and change. This second definition fits research whose purpose is theory building and not primarily descriptive.

Induction is the movement from data to concepts, which is difficult to do in a 'pure' way but does represent an attempt to put aside researchers' own views and do active listening and open-minded observations in interviewing, observations, and document analysis in order to discover aspects of phenomena that researchers may not have anticipated.

Practice is any form of social work that involves face-to-face interaction with service users. This includes work in child welfare, children's mental health, shelters, group homes, and residential treatment programs, therapy with families, couples, and individuals, group work, community organizing, and in the many other domains in which social workers ply their craft.

Since GT, DQA, and the perspectives that are part of social work's self-definition have common roots, the kinds of research that GT and DQA are compatible with are social work specific and probably not focused research on practice. DQA and GT,

however, can contribute to focused research by providing information on the meanings of interventions to practitioners and research participants, experiences related to compliance with and fidelity to research protocols, the various adjustments practitioners make to established protocols in order to fit the situations of service users, and the various other conditions under which interventions take place. This is now the well-established view – that mixed methods, which used to be called multiple methods, can provide comprehensive views of social phenomena, including interventions (Creswell and Clark, 2010).

Deductive Qualitative Analysis

Deductive qualitative analysis is a form of research that (1) begins with theory, (2) recommends reflexivity statements, (3) uses negative case analysis as part of its sampling plan, (4) allows choice in terms of how researchers do coding, (5) recommends group analysis of data, (6) organize findings by themes, hypotheses, or concepts, and (7) does documentation and analysis of findings through a three level system of presentation of excerpts from data, researchers' interpretations, and analysis of how findings contribute to what is already known (Gilgun, 2005a, 2012a,b).

Initial Theory

The initial theory is either hypotheses or sensitizing concepts. The theory is typically developed through reflection on conceptual frameworks as defined earlier. By beginning with theory, researchers seek to develop further the theory or use the concepts of the theory to focus the research. The initial theory, whether hypotheses or concepts, is sensitizing in that it illuminates directions along which to look, while at the same time researchers purposefully seek information that will modify the concepts and hypotheses with which they began. They want the products of their research to fit the data. Both concepts and hypotheses, therefore, are provisional, subject to change and modification when evidence warrants it.

Many researchers assume that to do qualitative studies, they have to begin their research with no hypotheses to test and, in so doing, bypass hypothesis testing and theory-guided research. This widespread impression arose from the principles and procedures of early forms of GT where Strauss, Glaser, and Corbin (Glaser and Strauss, 1967; Strauss and Corbin, 1998; Corbin and Strauss, 2008) advised researchers not to begin with theory, but to begin research inductively, with the assurance that eventually theory would emerge through the procedures that they delineated. The developers of GT were concerned that researchers would impose theory on findings, rather than develop theory from findings.

There is good reason to begin research with initial concepts and theory. Researchers interested in particular theoretical models cannot and should not be expected to start anew, or act as if they do not already know something about their areas of interest. They can test theories qualitatively or use concepts to guide their research. Furthermore dissertation committees are unlikely to approve studies that do not build on what is already known nor are funders inclined to commit money to such studies. Even Strauss (1987) softened his earlier stance when he advised researchers who do GT to conduct preliminary studies to write proposals that they intend to submit for funding.

DQA recognizes these issues and provides guidelines for doing research that begins with an initial conceptualization that can range from a parsimonious model or theory to a rather loose set of ideas. I coined the term *deductive qualitative analysis*, after trying out many others, because my experience led me to conclude that having a prior conceptual framework is an important way to do qualitative research (Gilgun, 2005a, 2012a,b). I pieced together the procedures of DQA from earlier work on analytic induction (Cressey, 1953; Lindesmith, 1947; Znaniecki, 1934) and the thinking of philosophers John Dewey (1910) and Karl Popper (1969).

Reflexivity Statements

As discussed earlier, reflexivity statements show respect for researchers' personal and professional experiences from which they develop compelling research questions. Lindesmith (1947) makes an excellent case for the role of experience. They have an important role to play in evidence-based practice (Gilgun, 2005b).

Negative Case Analysis

Imposing theory on findings is poor practice. Beginning a study with no theory is one way to attempt to avoid this, but it is not foolproof. Researchers can add theory to their study at any time and force data to fit the categories of the theory at any point in the research process. DQA uses a procedure called negative case analysis to avoid forcing. Negative case analysis guides researchers purposefully to seek data that undermine their developing theories, rather than seek data that support the theory with which they began. Cressey's (1953) analysis of embezzlement illustrates how to do negative case analysis. Negative case analysis fits with Popper's (1969) idea of conjectures, refutations, and reformulations that Popper believes is the fundamental process of science.

Coding, Analysis, and Interpretation

In DQA, coding, analysis, and interpretation can be done any number of ways, such as the generic three-level codes described in Strauss (1987) and Strauss and Corbin (1998) or the kinds of analysis associated with interpretive phenomenology (Benner, 1994), which includes several kinds of analysis such as the identification of themes and the construction of exemplars and paradigm cases. Through experience, I have found group analysis of data to be effective for testing emerging understandings against the interpretations of others who have different life experiences, training, knowledge, and other perspectives. Group analysis also brings in multiple perspectives. This strategy is traditional, going back at least to Booth's studies of the London poor at the end of the nineteenth century (Webb and Webb, 1932). Olesen et al. (1994) provided an account of group analysis within the Chicago tradition. Group analysis helps to ensure that findings will account for the complexity and variations of social phenomena.

Some Background

In earlier writings, I used the term *analytic induction* to describe what I am now calling DQA (Gilgun, 1995, 2012b). Analytic induction is the procedure that researchers used on classic studies, such as the work of Becker et al. (1961), Cressey (1953), and Lindesmith (1947). I prefer the term *deduction* because induction is not possible as an initial step in the doing of research. In order to sort particular observations from innumerable possible observations, researchers do not begin as blank slates. Something helps them notice particular phenomena and not others. Even Glaser and Strauss (1967), widely considered premier and pioneering inductive qualitative researchers, acknowledge this in a footnote in their well-known text. Induction, then, is a misnomer in this type of research.

I also decided to put together procedures that I call DQA to invite researchers trained in logico-deductive methods to do qualitative research. For too long, the idea that qualitative research does not begin with a conceptual model has been dominant. Social work researchers have a wealth of theory- and research-based knowledge that can be put to use in qualitative studies. Their results will be closely linked to respondents' experiences and may be useful to policy, programs, prevention, and intervention.

Furthermore, I encourage DQA in my teaching and writing to debunk the widespread perception that analytic induction is based on obsolete philosophies of science that guide research toward seeking causal and universal hypotheses that are invariant. The term has a 'spoiled identity' (Gilgun, 2005a, 2012b). Some commentators (Robinson, 1951; Vidich and Lyman, 2000) dismissed analytic induction for this reason. As a result, the term *analytic induction* has rarely been used for about 50 years. Researchers who want to carry out theory-guided qualitative research have few if any guidelines for doing so (Gilgun, 2012b, 2005a).

Grounded Theory

GT has so many forms that researchers must specify the type that they are using. Originally, GT was a method for developing theory that begins in an open-ended way where researchers enter the field in order to identify theoretical concepts that emerge from data (Glaser and Strauss, 1967). The originators were clear that researchers must not impose theory on data but allow the theory to emerge. They also took a stand against 'grand theories' that they viewed were detached from the empirical world. They coined the term *grounded theory* to designate a kind of middle range theory (Merton, 1968) where researchers develop theory so that its links to concrete data are explicit. Theoretical sensitivity, theoretical sampling, and the constant comparative method were and, still are, part of GT. Theoretical sensitivity involves capacities for identifying concrete instances in data as part of preexisting theory (Glaser, 1978). Theoretical sampling involves choosing the next case to investigate on the basis of its promise to expand upon the emerging theory. Constant comparison involves comparing data bits and associated concepts within and across cases in order to build and ground the theory.

As methodologists continued to develop procedures for GT, they made efforts to clarify these procedures. Eventually, doing GT began to appear prescriptive, such as the use of the conditional matrix that Corbin and Strauss (2008) described as "a coding device" (p. 183) and "a conceptual guide" (p. 193) that directed researchers to account for processes such as actions, interactions, and the conditions and consequences of social processes. The matrix was intended to help researchers to account for person–environment interactions and to make decisions about which analytic threads to follow and which situations and persons to sample, in other words, as a guide to theoretical sampling and the development of core categories that became the concepts of the theory under development.

Strauss and Corbin specified other procedures as well, such as the three-level coding scheme of open, axial, and selective coding (Strauss, 1987; Strauss and Corbin, 1998; Corbin and Strauss, 2008). They have an extensive set of terms, which can take time and practice to understand and master. Schneider's (2012) work on women's experiences of childbirth is an example of a traditional approach to analysis using concepts from the conditional matrix. She coded for "properties, dimensions, and relationships between concepts" (p. 217). How she collected her data was not traditional GT because her data set was composed of responses to open-ended questions on an online survey.

By the early 1990s, Glaser (1992) broke away from the directions that Strauss and colleagues were taking. He became concerned that the newer procedures were doing exactly what the first iteration of GT as set forth in the original work (Glaser and Strauss, 1967) was meant to combat, which was imposing theory on data and not allowing theory to emerge. Other methodologists, too, were concerned about the prescriptive nature of GT. Denzin (1997), for example, abandoned GT for decades, because he became swamped in its technicalities. He followed instructions that Strauss delivered in person about the constant comparative method, comparisons across field sites, and the search for emerging theories, indicators of concepts, and links to theory. Denzin instead followed other Chicago School traditions related to the less prescriptive and more descriptive style of research that Chicago methodologists called *fieldwork*.

After 40 years, Denzin (2010) came out as an enthusiastic promoter of a particular form of GT: collaborative, constructivist, and critical. After all those years, Denzin saw that GT does not have to be prescriptive, and researchers can use it in adaptable and open-ended ways to develop descriptive and conceptually rich understandings of human situations. Its open-endedness permits researchers to adapt it to their own particular methodologies and conscious and unconscious biases. Denzin adapted GT to serve his commitment to social justice issues in research, which includes researcher collaborations with participants, the importance of local knowledge, and, once the research is completed, advocacy for social change.

Finally, there are confusions about GT as method and as product. Bryant and Charmaz (2007) distinguished between grounded theory methodology (GTM) and GT. The former marks the use of generic procedures associated with GT and the latter is GT as product. The generic procedures include, among others, the coding scheme and the constant comparative

method. The term *grounded theory* has become a big tent, but it is confusing to label procedures as GTM when they simply are strategies for doing qualitative research and are generic. As Bryant and Charmaz (2007) pointed out, researchers commonly label as GT work done using generic procedures, such as coding or cross-case comparisons (constant comparative method). In the most recent edition of their coauthored book, Corbin and Strauss (2008) shifted toward a more middle position when they stated that use of prior theory is acceptable in GT, as long as the theory is provisional. The authors did not specify how to use prior theory in GT.

Fieldwork and the Chicago Tradition

Glaser, Strauss, and Corbin did not explore or explain the intellectual roots of GT. The brief discussions they had of the Chicago tradition were dismissive, such as disparaging negative case analysis while giving a superficial account of it (cf Glaser and Strauss, 1967). What Denzin now calls GT is a good old-fashioned Chicago School of Sociology methodology. Members of the Chicago School did not name the overall approach to research except to call it fieldwork (Strauss, 1992), although they did name the procedures of analytic induction including negative case analysis and group analysis of data.

Fieldwork is generally descriptive, although infused with conceptual material, and characterized by multiple methods and the other qualities associated with Chicago research, as already discussed. Examples abound: Frazier (1932) and Thomas and Znaniecki (1918–1920/1927). Bogdan and Biklen (2007), among others, have been a force in keeping the traditions of Chicago descriptive research alive.

Applications to Practice Research

GT and DQA can facilitate the development of theory and conceptually rich descriptive research useful in many types of social work practice settings. The kind of research that these approaches facilitate is social work-specific research, which incorporates principles associated with social work's self-definitions and that in turn has connections to the Chicago School of Sociology.

I searched the database, *Social Work Abstracts*, to see what products researchers have developed using GT and DQA. I used the search term *grounded theory*, and the search resulted in more than 200 articles. The term *deductive qualitative analysis* yielded naught. Yet, as I read the articles, I saw that several researchers who said they did GT actually used procedures that fit definitions of DQA, while others did descriptive research that in the Chicago tradition is fieldwork. Some were unclear about methods to the point that it was difficult to know the procedures they followed, although they wrote that GT was part of the mix.

In this section, I note this state of confusion and attempt to clarify. At the same time, I want to show what DQA and GT bring to social work research. This is a dual agenda, but I could not figure out how to talk about products without also noting whether DQA or GT is associated with the research I discuss.

The following citations are representative articles from my search using the term *grounded theory*. These articles presented descriptive research whose purpose was to understand social workers' experiences with specific populations (Saini et al., 2012), the experiences of specific populations who are in the care of social workers (Barney and Buckingham, 2012), concept development (Leece and Peace, 2010), and research whose purpose is to influence public policy and programming (Leece and Peace, 2010). These articles exemplify social work-specific research and are not focused research on social work interventions.

Some of the articles fit DQA better than GT. Others were labeled GT, but the researchers did not produce a theory and most did not report beginning the research in an open-ended way, both defining hallmarks of GT. Few if any used the terms *theoretical sampling* and *constant compassion*. They used coding schemes associated with GT, but coding schemes do not make a GT study (cf Bryant and Charmaz, 2007).

In some cases, researchers reported that they did a GT study, but their methods are exemplars of DQA. For example, Leece and Peace (2010) began their research with concepts and sought to further develop these concepts. They called their study *grounded theory* but its features are closer to definitions of DQA than GT. Their work fits definitions of DQA and not GT because they began with theory, their purpose was to develop theory, they focused on the theory throughout the research process, and their findings were elaborated theoretical concepts. They did not do negative case analysis, which is important to do when beginning with theory, and they did not have a reflexivity statement, which is recommended in DQA.

There are many other examples of social work research that authors label as GT when they actually use the procedures of DQA, e.g., Barney and Buckingham (2012) who sought to develop the concept of spirituality. The confusion between GT and GTM as Bryant and Charmaz (2007) noted is present in social work research as is confusion between DQA, GT, and GTM.

Conclusion

GT and DQA are important ways to do social work-specific research. Their products are closely linked to the lived experiences of service users and service providers, making findings useful and usable to practitioners. The usefulness of GT and DQA is related to an intellectual heritage they share with social work.

Abstract

Collaboration across countries poses challenges relating to the understanding of the objectives and outcomes of research studies as well as the ethical issues arising from the engagement of researchers and study populations with varying cultural backgrounds. Cross-cultural dimensions pose difficulties for researchers' understanding and observance of ethical and legal considerations. These considerations may apply to ways of dealing with research subjects, handling data, research design and methodology, and negotiating authorship credits. As concepts such as autonomy, privacy, and informed consent take on variable meanings, researchers should take the variability into account in order to minimize ethical complications.

Introduction

Research ethics encompasses norms of conduct and concomitant discourse pertaining to the delineation of good or acceptable from bad or unacceptable behavior in research. Some norms (e.g., respect for life) are widely regarded as universal, as they cut across different societies. A few are arguably more pervasive and more commonly observed (e.g., 'human rights' as articulated in the Universal Declaration of Human Rights) in some cultures than in others. A study of these norms – as they are practiced in, or applied to research – is also within the scope of research ethics.

Particular cultures are usually defined in terms of socially transmitted behavioral patterns, including beliefs, arts, religions, institutions, ways of life, thinking and knowing, and other products of human labor. With boundaries that are flexible and permeable and features that are dynamic, one culture can neither be adequately described without implicating another, especially today in an era of globalization and ubiquitous information and communication technologies (Brody, 2009), nor is a culture adequately describable without implicating other societal domains like politics and economics. Cultures of large populations are so complex that they also support diverse ethnicities and dynamic subcultures. Thus, 'cross cultural' could refer to cultures not only across but also within societies.

In this article, cross-cultural dimensions of research ethics are described in three different but interrelated domains: contextual concerns, conduct of research and research dissemination, and international initiatives addressing cross-cultural aspects of research.

Contextual Concerns

Differences among researchers, among research participants, and between researchers and participants are complex, multidimensional, and polycontextual. Such differences are amplified by the growth in international research as well as by long-standing divides of culture, research and scientific traditions, and diverse regulatory regimes of research.

Growth of International Collaborative Research

The increasing number of research publications with multicountry authorship clearly indicates the correlative growth of multicountry research collaboration. In turn, the growth of research collaboration across countries poses challenges relating to the understanding of the outcome of the studies as well as the ethical issues that may arise because of the engagement of researchers and study populations belonging to different nationalities with varying cultural backgrounds. The cross-cultural dimension makes it imperative for researchers to be able to navigate cultural boundaries in a way that enables them to conform to ethical and legal considerations. In practice, these considerations may apply to ways of dealing with research subjects, handling data, deciding on research design and methodology, managing workloads and working habits, and negotiating authorship credits, especially when different research teams and different research sites are involved.

For example, research design can pose many difficulties, including those that pertain to the meaning of concepts and the language that is used. Thus, in health-related social research, there may be discrepancies in the meaning given to words like 'disease' or the names given to particular diseases. There are bound to be variations in the understanding of conditions such as dementia, leprosy, or HIV/AIDS, particularly because of the emotive (if not pejorative) content that these words can have in different social contexts. Certain scientific concepts (like placebo and randomization) can also defy translation into local languages. Insistence on translation may even complicate communication between researchers and research participants (Tindana et al., 2006).

Cultural and linguistic differences as well as the ethical and legal issues that these give rise to can have profound roots. Moral values grow together with a society's sense of right and wrong. A particular society's values and sense of right and wrong are informed by the cultural context in which they grow. Researchers need to be mindful not only of the differences in cultural contexts in which research is carried out but also of the deeper roots that these cultures have in moral values and a communal sense of right and wrong.

East–West

One contrast that is often cited to illustrate cultural differences is that between East and West. There are those who hold the view that what may be regarded as Western medical research has been guided by prevailing moral philosophies in the West; Eastern medical research has had roots in the prevailing moral philosophies in the East. Put in this way, the view is obviously oversimplified. However, it could be useful in paving the way for a more specific and nuanced deconstruction of complicated circumstances.

Cultural values affect ethical standards not only by virtue of their having a Western or Eastern character but also in many other respects. The boundaries between Western and Eastern values are seldom clear insofar as they apply to research subjects or research contexts. Geographical boundaries have proven to be very permeable and cultural influences have penetrated boundaries very easily, courtesy of travel and communication technologies. Western moral philosophies have influenced Eastern ethical standards and Eastern moral philosophies have influenced Western ethical standards. Moreover, cultural values and traditions are emerging from a collective sense of right and wrong in communities and social groups that are not necessarily bound geographically, although geographical proximity is still a factor that can influence the values that people acquire.

Insofar as research and science have to contend with value differences between and among researchers and subjects or participants, they are inevitably cross-cultural. While there are value differences, there are also commonalities. Given the porous, dynamic, and nonimmutable nature of cultures, we are seeing more and more cultural hybridization. For the sake of naming convenience and simplification, however, references here are made to 'Western' and 'non-Western' cultures more as dominant tendencies rather than as hard and fast categories. Complicating the understanding of these terms are economic and technological dimensions of expressions like 'developed' and 'developing' as well as 'first world' and 'third world.' While not interchangeable with 'Western' and 'non-Western,' 'developed' and 'first world' countries often subscribe to dominant 'Western' standards. These are to be understood not so much as oppositional terms but rather as dynamic tendencies in light of cultural hybridization in the social world.

Research and Science as Culture

The US Code of Federal Regulations (CFR) Title 45 Part 46 defines 'research' as "a systematic investigation, including research development, testing and evaluation, designed to develop or contribute to generalizable knowledge." Operationally 'research' is inseparable from science as both have to do with knowledge of the world and procedures for obtaining such knowledge. However, the definition of 'scientific research' is far from neutral. Insofar as research and science are highly organized human social activities, they take off from certain cultural or ethnic assumptions. Among these assumptions are values usually deemed 'universal' by the dominant culture. But some practitioners have pointed to the ethnographic features of science (as championed in many research institutions today) marked by specific conventions, boundary techniques, and values (Franklin, 1995). In the face of differences and variations in practice, instruments of control in the form of laws, declarations, conventions, and guidelines have been promulgated. In turn, these have given rise to behavioral expectations for the conduct of research throughout the world.

However, the resulting ethical codes and guidelines (and the research paradigms that inform them) are increasingly deemed inadequate in addressing the issues arising from cultural differences in research practice (Marshall and Batten, 2003). "Research ethics" norms (as currently articulated in international instruments) are facing the challenge posed by local communities that see research norms as a form of 'local knowledge.' Thus, some of these norms are encountering resistance as they are applied beyond the 'local' culture and regulators or practitioners seek their broader implementation. When international instruments are presumed to have universal applicability or absolute character, tension with the unique cultural features that form part of a local culture's identity arises (Christakis, 1992).

Internationalization and Regulation of Research

To many, research ethics signifies regulation. If one is to be an ethical researcher, one has to be able to comply with regulations intended to ensure ethical conduct. Conversely, there is the view that the lack of regulation has allowed researchers to behave unethically. Regulation in the way that it is known today was an offshoot of the findings at the Doctors Trial of 1946–47, which happened within the context of the Nuremberg Trials for Nazi war criminals. The resulting document, the Nuremberg Code (1949), outlines the ethical principles for research involving human subjects, including voluntariness, informed consent, beneficence, and nonmaleficence. Succeeding codes or regulations, like the World Medical Association's (2013) Helsinki Declaration and the US Code of Federal Regulations (CFR) Title 45 Volume 46, have been influenced by the Nuremberg Code. The cultural import of such development lies in the adversarial context of the origins of these regulations in the West. Its narrative has been about unscrupulous researchers doing experiments that sacrifice human concerns in the fulfillment of debatable scientific goals. A set of research ethics codes is therefore needed to help prevent these researchers from harming human subjects. The narrative forms part of the "human subjects protection" ethos of international regulation of research. Essentially researchers are to demonstrate before ethics committees that, in part, they are not out to harm people. While the injunction against harming research subjects may be inescapable in international research regulation, its overarching narrative, and adversarial context of origin could be antithetical to relationship building in some non-Western cultures.

Initial efforts at the ethical regulation of research showed a tendency for consensus building. However, as implementation of international declarations and guidelines spread beyond the need to address the catastrophic consequences of war-time research involving human subjects, the scientific community gradually realized the necessity of coming to terms with the cultural nuances that made universal norms complicated in their practical application.

A major concern in the internationalization and regulation of research is the applicability of foreign codes and guidelines

to local settings or their compatibility with local laws, rules, practices as well as with local institutional mandates and priorities. For example, genetics research projects have been undertaken in rural areas in developing countries that encounter difficulties when observing U.S. Institutional Review Board (IRB) guidelines because of differences in sociocultural norms, religious and other traditions, language, and geography (Sampson et al., 2013). Such differences challenge the applicability of IRB concepts and principles in non-Western societies. In comparison, codes and guidelines that are intended to apply globally such as those originating from the World Health Organization – Council for International Organization of Medical Sciences, the United Nations Educational, Scientific and Cultural Organization, and the World Medical Association (2013) are usually subjected to broad international consultations that take cultural differences into account before they are issued. Nevertheless, occasional challenges can still be encountered in some cultural contexts.

Some of the challenges have to do with the application of guidelines pertaining to privacy. International guidelines and codes of ethics require health research to respect the confidentiality of health information. However, rigid observance of privacy requirements in patient-healer relationships has been shown in ethnographic research to lead to discomfort among research participants (Monshi and Zieglmayer, 2004). Insistence on 'privacy' could reflect an ethnocentric bias that does not carry well in non-Western contexts where what would otherwise be regarded as 'private' and 'confidential' information could readily be shared according to traditional practices.

There could also be a limited understanding of the relationship between ethical guidelines and local research ethics committee regulations (Bhutta, 2002). Where there is a limited capacity among the locals to conduct research, international researchers are more likely to dictate the research agenda. Hence, research questions could easily be more about problems of people from sponsoring countries and less about raising local standards of care. It is easy for such research to gloss over the significance of local community participation and the sharing of benefits with the host community.

Conduct of Research and Research Dissemination

Informed consent is generally regarded as the bedrock of permissible conduct of Western scientific research involving human subjects. It is important to understand the cultural context where informed consent is sought and given. Because informed consent has been a crucial factor in the ethical implementation of research, it has been the focus of much discourse pertaining to the significance of cultural differences in appreciating research ethics. For example, a lot has been said about "inadequacies" in the implementation of informed consent requirements in some developing countries. The contrast between 'developed' and 'developing' countries is ordinarily understood in relation to economic progress. Yet, the economic differences are also intertwined with cultural features, some of which have economic roots themselves. Informed consent procedures often are institutionalized and well-regulated in developed countries. Regulations can be so specific that researchers are left with little room to improvise when informed consent procedures, tried and tested in developed countries, have little chance of success in developing countries. Problems have arisen in situations where developing countries or communities are determined to preserve crucial aspects of their identity and are thus unwilling to yield to foreign informed consent conventions that tend to undermine their culturally determined values and practices.

Autonomy is a crucial factor in determining the validity of informed consent. The exercise of autonomy is generally regarded as a necessary condition for the exercise of free consent. It is in relation to the individual subject that autonomy is commonly gauged. The individual person is the subject of assessment when efforts are made to determine whether there is sufficient understanding of relevant information given. However, the individual is not always regarded as the basic social unit for decision-making in every given community or society, even with respect to matters regarding a particular individual as a subject of research. Thus, developed country researchers may be making a mistake when they invoke autonomy in behalf of an individual in a developing country where the family – rather than the individual – is regarded as the basic unit of society.

In developed countries, the informed consent process requires the involvement of individual participants, except where these participants are not legally competent. Even when representatives of a community are involved (e.g., in population studies), individual consent is still a requirement. The rule generally observed is that community consent cannot override individual consent. Community consent is often regarded as a necessary but not a sufficient condition to validate consent. However, in many developing country contexts, the starting point for the informed consent process has to be a social unit that is bigger than the individual. In resource-challenged developing country situations, individual lives could be so interdependent (e.g., economically, in matters of home-based health care, or in many aspects of day-to-day activities) that people feel they cannot afford to be making decisions on their own. Individual participants may find themselves confronted with a research project that has been approved in their behalf already by their representatives. In theory, the participants' consent may be individually required; in practice, they either defer to the community decision as they are used to, or they find community pressure irresistible, but also as an inevitable feature of communal life.

Overlapping with the developed–developing country duality is the contrast often made between Western and non-Western moral philosophies. The individual is regarded as the moral agent who is expected to make decisions, make those decisions on the basis of reasons, and assess those reasons as an act of self-determination. This is thought to provide the framework not only for evaluating the ethics of research but also for undertaking research itself.

On the other hand, many non-Western societies have situated informed consent within the framework of a community decision-making process. This is why decisions to participate in biomedical research have had to be made by families rather than solely by an individual.

Cultural nuances are also significant in dealing with documentary requirements and signatures for informed consent. In resource-challenged societies where illiteracy is common, the

value of written documents and signatures is limited. The assertion of an individually centered decision to participate or not in research could result in problems that may linger long after a research project has been completed and the researcher has left the research site. Researchers may find it difficult to insist that informed consent documents be signed individually. Lengthy and complicated forms are difficult to process for those who may be unduly pressured to affix signatures. One could see how such a value (or disvalue) does not contribute to the flourishing of an individual or of the community to which that individual belongs.

Moreover, signatures and the ritual of signing have specific meanings for people in some developing country contexts. One must understand those meanings and consider alternative procedures for consent taking that are sensitive to those cultural peculiarities. Various ethnic groups may perceive the signature requirement as a challenge to a cultural perspective that is founded on the reliability of the spoken word.

Human subjects may also have other reasons to be intimidated by the idea of having to sign consent forms. There have been cases where people belonging to certain communities could not readily accept the idea of signing consent documents because they had previously lost parcels of land by affixing their signatures to a document (Creed-Kanashiro et al., 2005). There are also accounts of people developing a fear of signing documents because of negative consequences that doing so entailed when they were still living under communist regimes (Liamputtong, 2010).

In relation to these examples, being developed or developing are used with reference to economic conditions rather than to cultural or social values. It would be easy, but wrong, to understand these terms to refer to ethical values or even to research capacity. The research practices associated with developing countries are not necessarily lacking in development. Neither are the cultural values that may be reflected in those practices. The rejection of written documentation among small ethnic groups should not be treated condescendingly as a manifestation of backwardness.

In addition to the examples cited above, the refusal to provide acceptable documentation of consent could be indicative of a high regard for the spoken word ("I need not affix my signature if I have already given my word") or of a fear of the possibility of the signed document being used against the signatory in a negative way in future. In these contexts, 'developed' is not necessarily better than 'developing.' 'Developing' is not necessarily just a stage leading to the 'developed' world, as those in developed countries know it at present. There are many regulations that cannot simply be applied and many practices that cannot simply be adopted in developing countries just because these have been successful in developed countries. Adaptation is necessary and researchers have to be creative enough to try alternative procedures. In dealing with illiterate populations, researchers have used audio-visual aids such as photographs, diagrams, and video clips to explain a research project's aims, methods, and procedures. Video recordings have also been used to validate verbal consent when the latter is obtained in lieu of a signed written document. Taking steps such as these helps ensure that challenges to the cultural aspects of ethical research are overcome.

Content and Understanding of Consent Documents

There are also problems that pertain to the content and understanding of consent documents. Obviously, it is important for the informed consent process to be documented using the signature of the participant and under the guidance of ethics review committees. However, the information given, especially across cultures, can be misunderstood or misinterpreted. The translation from one language to another could distort meaning or significance and give rise to a decision regarding participation that is based on distorted information or on a misguided assessment of benefits and risks. Studies have already shown that even within a single country using a single language the information regarding a research proposal could easily be misunderstood. This danger is increased when research is carried out across national boundaries and participants have to try to understand a translation.

Research Publication and Utilization

The conduct of research and research dissemination are essentially two sides of the same scientific enterprise. Once research is conducted, the expectation is for researchers to publish study results in peer-reviewed journals. In this 'assembly line' of knowledge production, journal publishers become *de facto* knowledge gatekeepers.

Journal Publishers as Gatekeepers

Medical journal editors have played the role of ethics gatekeepers by requiring that authors of articles submitted for publication should declare that their research project had prior approval by an ethics review committee and that the investigators complied with the guidelines expressed in the Helsinki Declaration. By requiring compliance with international ethical guidelines intended to protect human research subjects, editors and publishers have encouraged investigators to observe culturally sensitive ethics requirements, while at the same time supporting international collaboration indirectly. Some journals have promoted culturally sensitive manuscript submission policies by requiring consent for publication of case reports or case series regardless of the country from which the manuscript was submitted, giving human subjects a chance to review information pertaining to them before being released for publication (Bevan and Miller, 2005).

While investigators seem to be able to respect confidentiality of information regarding individuals without much difficulty, they could more easily overlook confidentiality requirements for information about groups of individuals or communities. For instance, one may come across a study reporting that a worryingly high prevalence rate for urinary tract infections has been observed among women in a particular community or that lorry drivers plying a certain route in one country have been found to visits brothels at an alarming rate during overnight stops.

In response to the above concerns, some have suggested that sensitive research data should not be published when there is a request to that effect from the community. An example is given of a study among the Hmong diaspora in Australia where an investigator was asked not to write and elaborate about certain aspects of rituals that could harm the cultural integrity of the community. A suggestion is thus made for researchers to

avoid publishing sensitive identifiable information that may put the participants at risk of unwarranted scrutiny or even physical and social harm by authorities or security forces. The investigator further recommends the use of pseudonyms or the adoption of fictional names for places in order to help protect subjects. In some cases, the omission of some research data from a publication may be necessary to minimize danger to research participants (Liamputtong, 2010).

Assessing Benefits of Research: Cross-Cultural Aspects

In research involving human subjects, the expectation does not end in publication. Direct benefits to study participants are looked into.

The contrast between developed and developing country cultures shows up in the assessment of benefits resulting from health-social science research. One study done in Mexico revealed that while research subjects derive benefits from the studies in which they assume the risks, these benefits are minimal when compared with health, financial, and academic gains that accrue to sponsors and future patients in resource-rich countries. The interaction between developed country sponsors and investigators and developing country research subjects reveals a culture of exploitation (Páez and Garcia De Alba, 2009).

In this particular example, the investigators reviewed 34 multinational, multicenter research protocols and found that the protocols did not specify benefits for the host institution or for the host community. There was also no reference to post-trial access to successfully researched therapies. These were expected to be too expensive for the Mexican population in general, making them culturally irrelevant. The authors also claimed that the studies did not address the greatest health priority for the country, which was insufficient health care coverage (Páez and Garcia De Alba, 2009).

The significance of culturally mismatched benefits has been observed elsewhere, leading to the observation that relevant and meaningful health research in developing countries has to be able to promote equity and develop local bioethics capacity, especially in the face of continuing globalization and the genomics revolution (Bhutta, 2002).

International Initiatives Addressing Cross-Cultural Concerns of Research

Given the complexities involved in social and behavioral research, it would be almost impossible to find clear-cut solutions to the cross-cultural concerns discussed above. However, there have been various initiatives to develop international consensus at the level of general principles. The most prominent of these have been associated with guidance mechanisms to help promote a culturally sensitive implementation of research projects and protect the welfare of research participants across societies.

International Instruments

Faced with cultural concerns complicating the assessment of ethical issues in research, international agencies and organizations have worked out guidelines to try to address the difficulties from a multicountry perspective. Some of the issues that have been identified are being addressed by regulatory instruments such as UNESCO's Universal Declaration on Bioethics and Human Rights (2005), which deals with ethical issues related to medicine, life sciences, and associated technologies as applied to human beings, taking into account their social, legal, and environmental dimensions. Providing guidance to UNESCO's member states, it provides guidance regarding decisions or practices of individuals, groups, communities, institutions and corporations, public and private. Article 12 highlights the importance of giving due regard to cultural diversity and pluralism while at the same time warning against invoking such considerations in a manner that infringes upon human dignity, human rights, and fundamental freedoms.

The Declaration also provides that multicountry research should be the object of an appropriate level of ethical review in the host countries and the country in which the funder is located. In addition, the Declaration maintains that transnational health research should be responsive to the needs of host countries, and that the importance of research contributing to the alleviation of urgent global health problems should be recognized.

The assessment of research benefits could also be distorted by a failure to take into account cross-cultural differences and disparities among research populations. Thus, we can understand the Universal Declaration's position that terms for collaboration and agreement on the benefits of research should be established with equal participation by researchers, research communities, funders, and any other party to the negotiation.

The International Ethical Guidelines for Biomedical Research Involving Human Subjects (2002) issued by the Council for International Organizations of Medical Sciences (CIOMS) is also particularly sensitive to cultural differences relating to the ethical practice of research. Dealing primarily with biomedical research, the guidelines aim to reflect the conditions and the needs of low-resource countries involved in multinational or transnational research. CIOMS emphasizes the need to obtain research permission from a community leader, a council of elders, or another designated authority and thereby show respect for local customs. The Guidelines also note that since many people in all cultures are unfamiliar with, or do not readily understand, scientific concepts such as those of placebo or randomization, sponsors, and investigators should develop culturally appropriate ways to communicate information that is necessary for adherence to the standard required in the informed consent process, and should describe and justify in the research protocol the procedure they plan to use in communicating information to subjects. Referring specifically to collaborative research in developing countries, CIOMS says that the research project should include the provision of resources to ensure that informed consent can indeed be obtained legitimately within different linguistic and cultural settings.

As for research in populations and communities with limited resources, CIOMS provides that in a population or community with limited resources, the sponsor and the investigator must make every effort to ensure that:

- the research is responsive to the health needs and the priorities of the population or community in which it is to be carried out; and

- any intervention or product developed, or knowledge generated, will be made reasonably available for the benefit of that population or community.

Responding to Local Healthcare Needs

Also reflecting an emerging international consensus regarding research involving people in low and middle income countries, the Wellcome Trust Guidance Notes (2013) on Research Involving People in Low and Middle Income Countries reinforce the view that investigators must demonstrate that their research is responsive to the healthcare needs or priorities within that country. Taking the example of malaria, tuberculosis and HIV/AIDS, the Trust says that the outcomes of such research should be likely to lead to relevant and sustainable health benefits to people in those areas where the research is undertaken. In this regard, it considers research to have local applicability where:

- insofar as it can be estimated, the prospective treatment will or might foreseeably become available to local patients on a sustainable basis;
- the prospective treatment will or might foreseeably become affordable locally; or
- prospective treatments could be delivered within existing structures, or structures that are to be (or could readily be) developed. For example, if a prospective treatment involved administering medication via a particular medical procedure, local healthcare staff would need to have appropriate expertise. If such expertise were neither available nor going to become available in the foreseeable future, careful consideration would need to be given as to how appropriate training should be arranged.

Also relevant in this respect are guidelines issued by UNESCO's Management of Science and Technology Program (MOST) (1994) aiming to draw researchers' attention to certain areas in which conflicts between ethical principles and aims of the research might arise, provides that research should be carried out in full compliance with, and awareness of local customs, standards, laws and regulations. MOST stresses the need for all researchers to show familiarity with, and respect for the host culture. Where researchers are studying cultures, countries, and ethnic groups other than their own, they should make their research objectives particularly clear and remain aware of the concerns and welfare of the individuals or communities to be studied. Additionally, participants should be offered access to research results, presented in a manner and language they can understand.

Abstract

Since the adoption of The Nuremberg Code (1949) following Nazi medical experimentation in World War II, the ethical issues involved in research have been identified and are constantly developing and evolving. This article begins by providing a history of international research ethics regulations and guidelines and their development. It then provides a brief overview of research ethics issues such as ethics review procedures, and issues related to conflicts of interest. The article then explains and provides examples of mechanisms for the application of the three primary ethical principles involved in research ethics: respect for persons, beneficence, and justice. We conclude with a discussion of research ethics in an international and cross-cultural context.

The History of Research Ethics Regulations and Their Implementation

The first international regulation involving research ethics – The Nuremberg Code (1949) – was created in response to the atrocities in human experimentation conducted on prisoners by German Nazi doctors during World War II. Although the Nuremberg tribunal believed that the principles articulated in the Code were already widely accepted by the medical and scientific community, by codifying these principles, they established stringent and novel ethical regulations of human subjects research (Steinbock et al., 2003). The first principle emphasizes the tribunal's faith in informed and voluntary consent as the best means of protecting participant rights. Additional standards reflected the obligation of scientists to justify the scientific and social value of a study, avoid unnecessary physical and mental harms, and put in place adequate protections against harm. Almost two decades later, the World Medical Association published the Declaration of Helsinki – an international set of guidelines emphasizing the physician-scientist's primary obligation to promote the health, well-being, and rights of participants in medical research. This duty included protecting the life, health, dignity, integrity, right to self-determination, privacy, and confidentiality of personal information of research participants. For more information on international research ethics guidelines, *see* Ethics for Biomedical Research Involving Humans: International Guidelines.

Although professional organizations, such as the American Psychological Association (APA), began including general principles of research ethics in their codes of conduct as early as the 1950s, the Nuremberg Code and the Declaration of Helsinki had little impact on the regulation of medical and social science research until the 1970s following revelation, and subsequent public outrage, over the government-sponsored Tuskegee syphilis study. This study – which started in 1932 and involved 400 rural African-American men – was designed to determine what happens when syphilis remains untreated. Over the course of the 30-year study, the participants were neither informed nor treated when penicillin was discovered to be an effective treatment. When the details of the Tuskegee study were made public in 1972, public pressure led to US Public Law 93-348 calling for the formation of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research in 1974. After 5 years, the Commission produced the Belmont Report (DHEW, 1979), which established three ethical principles that became the foundation for the 1981 Code of US Federal Regulations 45CFR46 on the protection of human subjects in medical and behavioral research regulations. The Belmont principles include: (1) respect for persons, embodied in regulatory requirements for informed consent; (2) beneficence, embodied in regulations on the obligation to minimize risks and maximize research benefits; and (3) justice, reflecting in regulations requiring fair access of all populations to the benefits and burdens of research participation. For more information on research regulations in the US, *see* The Common Rule: US Regulatory Protections for Human Research Participants.

Shortly thereafter, in 1982, the Council for International Organizations of Medical Services (CIOMS), in cooperation with the World Health Organization (WHO) published the Proposed International Ethical Guidelines for Biomedical Research Involving Human Subjects, that demonstrated how ethical principles outlined in the Declaration of Helsinki could be applied, particularly in developing countries. The two subsequent revisions in 1993 and 2002 expanded on these guidelines in response to the globalization of medical and social science research. With advances in genomic science, the Council of Europe adopted the Convention on Human Rights and Biomedicine (also known as the Oviedo Convention) in 1997, which contains a chapter on the ethics of scientific research, in particular, the protection of persons undergoing research, the protection of persons unable to consent to research, and research on embryos *in vitro*.

Although many of the research ethics guidelines have originated in Europe and North America, WHO – the Special Programme for Research and Training in Tropical Diseases (TDR) in particular – established the Strategic Initiative for Developing Capacity in Ethical Review (SIDCER) in 2001, which was created to carry out its activities regionally, and has committees in Africa, Asia and the Western Pacific, Latin America, and the countries of the former Soviet Union.

The most recent internationally agreed-upon instrument on human subjects research is found in United Nations Education, Scientific and Cultural Organization's (UNESCO) Universal

Declaration on Bioethics and Human Rights (2005). One of the aims of the declaration is "to recognize the importance of freedom of scientific research and the benefits derived from scientific and technological developments, while stressing the need for such research and developments to occur within the framework of ethical principles set out in this Declaration and to respect human dignity, human rights and fundamental freedoms" (UNESCO, 2005: Art. 2(d)). The declaration lists 15 ethical principles, all of which can be applied to human subjects research, and many of which involve the principle of justice, including benefit sharing and equality.

Recognizing the strong biomedical basis for many of the international guidelines governing research, social science organizations began to develop specific standards for the conduct of social and behavioral research. As mentioned previously, the APA established their first ethics code in 1953, which was followed by the adoption of the American Anthropological Association's Statement on Problems of Anthropological Research and Ethics in 1967 (Hill, 1987). These early social science codes were written in aspirational language that was often challenging to apply uniformly to enforce research ethics practices (Fisher, 2013; Fisher and Anushko, 2008). It was not until the 1990s that specifically worded enforceable standards of conduct for research, teaching, and professional practice were included in regulations such as the British Psychological Society *Ethical Principles for Conducting Research with Human Participants*, the Canadian Psychological Association *Canadian Code of Ethics for Psychologists*, and the APA Ethics Code (BPS, 2010; Canter et al., 1994; CPA, 1991).

Specific ethical standards for social science research continue to be grounded in broad ethical principles. For example, Australia included social science provisions in their revised (1999) and current (2014) versions of their National Statement on Ethical Conduct in Research Involving Humans, which highlights principles such as research merit and integrity, justice, beneficence, and respect (NHMRC, 1999, 2014). The APA Ethics Code currently begins with a section outlining five general ethical principles: beneficence and nonmaleficence, fidelity and responsibility, integrity, justice, and respect for people's rights and dignity. Other codes, such as the Canadian Psychological Association's Code of Ethics, attempts to assist researchers prioritize ethical principles when they come into conflict, using the following order: (1) respect for the dignity of persons; (2) responsible caring; (3) integrity in relationships; and (4) responsibility to society (CPA, 2000). For more information on ethical dilemmas, research and treatment priorities, *see* Ethical Dilemmas, Research, and Access to Treatment.

The social science ethics codes continue to be revised in response to contemporary social issues. For example, in response to psychologists' involvement in harsh prisoner interrogations following the 11 September 2001 attacks, the most recent revision of the APA Ethics Code (2010) includes enforceable standards requiring psychologists to refrain from activities that could be used to justify or defend violation of human rights (Fisher, 2013).

Research Ethics Review

The regulations and guidelines discussed above stipulate that research involving human participants must undergo a review of its ethical acceptability prior to beginning the study. Research Ethics Committees (RECs) – referred to as Institutional Review Boards (IRBs) in the United States – are charged with the task of ensuring that the rights and welfare of the research participants are protected (Fisher, 2013). This includes achieving an appropriate balance between research risks and benefits; adequate informed consent procedures; fair procedures for the selection of participants; and special protections for vulnerable populations. Across the globe there are varying levels of review at the institutional, national, and regional levels, and having a good systems approach and clear guidelines will greatly help facilitate international research in the future (WHO, 2011). For example, in the European Union, it is legally required for all clinical trial research to be reviewed by an REC prior to the commencement of the study, in which it "comes to the conclusion that the anticipated therapeutic and public health benefits justify the risks and may be continued only if compliance with this requirement is permanently monitored" (EU Directive 2001/20/EC).

Conflicts of Interest

The trust and validity of research may be compromised by conflicting professional, personal, financial, or legal interests that can impair the objectivity of data collection, analysis, and interpretation (Fisher and Anushko, 2008). It is therefore necessary to establish ethical guidelines to avoid potentially harmful or exploitative conflicts of interest, as the impairment of objectivity can be detrimental to participants, the public, the institution, the funders, the investigator, and the integrity of social science. Such guidelines exist on the international (e.g., the Declaration of Helsinki and the CIOMS Guidelines) and national level (e.g., the National Institutes of Health (NIH) Office of Extramural Research's requirements in the United States). National regulations, such as the ones issued by the NIH, require every institution receiving federal research funds to have written guidelines for the avoidance and institutional review of conflict of interest (Fisher, 2013). Similarly, transnational regulations, such as the European Research Council (ERC) Scientific Misconduct Strategy, issued by the Standing Committee on Conflict of Interest, Scientific Misconduct and Ethical Issues (CoIME), exist to ensure that "grants are awarded on the sole criterion of scientific excellence," and that any incidences of misconduct are widely and publicly reported, in order for the ERC to "uphold high ethical standards in all its activities" (ERC, 2012; *see* Research Funding: Ethical Aspects).

Ethical Principles

Although regulations and guidelines vary in their emphasis on ethical principles necessary to ensure the protection of research participants' rights and welfare, three continue to serve as the most important and inclusive: respect for persons, beneficence, and justice. As social science research and regulations have developed, there has been a shift in the importance of the principles. The primary concern of the Nuremberg Code, for example, was the need for informed consent – which falls under the principle of respect for persons. But in recent times,

with advances in benefits derived from pharmaceutical and behavioral risk prevention research, there has been increasing emphasis placed on the principle of justice, particularly in terms of access to the benefits of research for vulnerable populations in economically developed and developing countries. This section will address each of the three principles in order of historical importance, along with the many mechanisms of application and the concepts that fall under each principle.

Respect for Persons

The ethical principle of respect for persons incorporates a respect for human rights and human dignity. More specifically, it involves treating individuals as autonomous agents, and ensuring that those with diminished capacities are entitled to added protections. Respect for persons is most commonly embodied in the requirements of informed consent and protection of confidential data.

Informed Consent

There are three components of informed consent: information, comprehension, and voluntariness (DHEW, 1979).

Information

Investigators are ethically obligated to provide research participants with the information necessary to ensure they can make an informed decision to agree or disagree to research participation. In the Declaration of Helsinki, for example, this information includes the aims, methods, sources of funding, any possible conflicts of interest, institutional affiliations of the researcher; the anticipated benefits and potential risks of the study and the discomfort it may entail; the post-study provisions; the right to refuse to participate in the study or to withdraw consent to participate at any time without reprisal; and any other relevant aspects of the study.

The exploratory and open-ended nature of participant observation, ethnographic, and other types of qualitative research raises questions about whether truly informed consent can be obtained for such studies (Marshall, 1992). In such cases, neither the investigator nor the participant may fully be aware of information that will arise during the course of discussion or observations. One way to address this issue is to clarify in advance that if unanticipated and sensitive issues emerge during the course of observation or discussion, a mutually negotiated re-consent procedure will be implemented (Fisher, 2004; Haverkamp, 2005). Additionally, researchers can view and seek informed consent as an ongoing, mutually negotiated process, rather than a single event (Grafanaki, 1996; Haverkamp, 2005; McLeod, 1996; Munhall, 1989; Raudonis, 1992; Rossiter et al., 1996; Smyth and Murray, 2000).

Comprehension

It is important that research participants not only receive accurate and necessary information about the study, but that the format and context in which the information is provided facilitates and ensures their understanding. For example, information should be presented to the research participants in a clear and organized manner, at an appropriate pace, and allowing for enough time for consideration and for participants to ask questions (DHEW, 1979).

In addition, the legal status and consent capabilities of research participants must be taken into consideration. Regulations and international and organizational guidelines require that investigators protect the rights of children who have not attained the legal status to consent, and adults with intellectual disabilities and other consent-compromising conditions. For example, guardian permission is required to protect children from consent vulnerabilities related to immature cognitive skills and lack of experience in health-care decision-making. At the same time, as articulated in the UN Convention on the Rights of the Child (United Naitons, 1989) respect for children's developing autonomy means that their assent to participate is also required. Under US regulations, guardian permission may be waived, however, if there is serious doubt that the guardian's interests adequately reflect the child's interests (e.g., research on child abuse), or in the case of adolescents, when research is related to health services for which they have attained the legal right to access independent of guardian permission. A report from the Ethics Working Group of the Confederation of European Specialists in Paediatrics (CESP) takes the stance that medical research involving children is not only acceptable, but necessary, as long as the following six guidelines are met: (1) the research is "important for the benefit of all children and should be supported, encouraged and conducted in an ethical manner"; (2) children have a unique set of interests; (3) research should only take place if comparable research on adults could not answer the same question; (4) if a research procedure is nontherapeutic then it must be likely to yield generalizable knowledge of vital importance; (5) all research proposals involving children should be submitted to an REC with experts in pediatric research; and (6) informed consent from a child, parent, or guardian should be obtained, as appropriate; when parental consent is obtained, the assent of school-age children who participate in research should also be requested by researchers (Sauer, 2002).

Similar protections are required for adults with health disorders that have required appointing a legal guardian. In many cases, however, adults with Alzheimer's disease or other progressive or developmental intellectual deficits may not have a legal guardian. In such cases, a trusted adult may serve as a consent advocate and provide support for the prospective participant's consent decision, which can protect against the potential for triggering a legal competency review for adults with disabilities who do not have a legal guardian (Fisher, 2002a, 2013). When investigators are unsure of the research participants' capacity to consent, they may use any number of assessment tools to determine the ability of the prospective participants to comprehend the nature of and their rights in the research. For example, the MacArthur Competence Assessment Tool for Clinical Research (MacCAT-CR) measures four increasingly complex aspects of research decision-making competence: the ability to (1) express a participation choice; (2) understand the purpose and nature of the research; (3) appreciate how participation will affect them personally; and (4) make a reasoned participation decision based on balancing risks and benefits (Grisso and Applebaum, 2001). For research

presenting only minimal risks to participants, the ability of a participant to understand and make a participation choice may be sufficient protection for ensuring they are making a choice in their own best interests. The latter two criteria may be more important as the risk of research participation increases.

For both children and adults with impaired cognitive capacity, participation decisions can each be enhanced through a model of ethical decision-making called goodness-of-fit ethics (GFE) (Fisher and Ragsdale, 2006; Masty and Fisher, 2008; Fisher and Goodman, 2009). According to GFE, consent vulnerability must be understood in terms of how well-informed consent procedures fit certain participant characteristics. GFE thus requires researchers to identify the research population's consent strengths and vulnerabilities, and fit the consent or assent procedures in ways that minimize vulnerabilities, enhance consent strengths, and provide consent supports when feasible (Fisher, 2013).

Therapeutic Misconception

A consent comprehension challenge arising in intervention research is therapeutic misconception (TM). First identified by Applebaum, Roth and Lidz in 1982, TM refers to two common, but incorrect beliefs held by research participants in randomized, controlled intervention research: (1) that their individual needs will be taken into consideration in group assignment and (2) that it is very likely that they will benefit therapeutically from the research participation. The TM tendency among prospective participants obligates investigators to clarify during informed consent the differences between the roles of a practitioner and those of an investigator, and the goals of treatment versus research. In addition, TM may be exacerbated by therapeutic mistrust in socially vulnerable or marginalized populations (Fisher et al., 2008). When working with social minorities, researchers must anticipate and effectively address the personal and collective history of abuses that these populations have experienced as research subjects (Fisher et al., 2002; Reverby, 2001). For more information on ethical implications and assessment and application of therapeutic effectiveness, *see* Therapeutic Effectiveness Assessment: Approaches in Contemporary Research.

Voluntariness

Informed consent must clarify the voluntary nature of participation, as well as an individual's right to withdraw his or her participation at any time during the study. Participants recruited from treatment centers, educational settings, social service agencies, or prisons may be understandably concerned that a refusal to participate in research may result in a denial of services, or other institutional retaliation. Investigators conducting research in such settings need to be vigilant in ensuring that such services will not be deprived, and clarifying such protections to prospective participants during consent.

While offering some form of compensation is often both ethical and necessary to fairly compensate individuals for their research participation time and effort and to guarantee an appropriately sized and representative research sample, it is possible – and crucial – for researchers to distinguish between 'due' and 'undue' inducements (Dickert and Grady, 1999; Macklin, 1999; VanderWalde and Kurzban, 2011). According to Emanuel (2005), compensation for research participation is only coercive when each of these four elements are satisfied: (1) the prospective participant is offered something that is perceived as valuable or desirable; (2) the incentive is so significant or in excess that it is irresistible in the context of the participation request; (3) the offer leads prospective participants to exercise poor judgment in an important decision, such as during recruitment or informed consent; and (4) the individual's poor judgment leads to the sufficiently high probability that the participation decision will lead to a harmful experience that 'seriously contravenes his or her interests' (Emanuel, 2005, p. 9). It is, however, important to note that strict prohibitions on undue inducements can lead to a paradoxical result: the less economically developed a community is, the fewer benefits can be offered, so as not to unduly influence the decision to participate (Schroeder and Gefenas, 2012). This paradox provides research sponsors with an 'ethical' argument for limiting benefits given to study participants in developing countries, and a challenge for RECs that must make decisions about this type of proposed research (Ballantyne, 2008; Schroeder and Gefenas, 2012).

There are several strategies for selecting an appropriate rate of compensation. For example, many institutions have adopted a set level of compensation for all research participants, while others have stipulated that a noncoercive financial incentive is the amount that an average, healthy volunteer would lose in work and/or travel time by the fair market value for the work involved (Fisher, 2013). Furthermore, consulting with members of the population that will be recruited for research participation about appropriate levels of compensation may assist researchers and their RECs determine whether the compensation is fair or coercive (Fisher, 2003; Flicker et al., 2007; Oransky et al., 2009).

Similar to capacity to consent, instruments exist to measure voluntariness. For example, Applebaum et al. (2009) identified offers, pressures, or threats related to research, as the types of influence most likely to reflect mechanisms by which one person can exert influence on the decisions of another, and constructed a brief instrument to assess voluntariness and motivation to participation.

Deception in Research

Deception in research involves many ethical challenges to adhering to the principle of respect for persons. One challenge is what Fisher (2005) has described as the 'consent paradox,' reflecting the moral paradox involved in intentionally deceiving a prospective participant about the nature of the research, thereby compromising the individual's ability to make a fully informed decision regarding research. In these situations, researchers conducting deception research intentionally give participants false information about the purpose and/or nature of their study, therefore leading individuals to erroneously believe that they have the autonomy to determine the type of experimental procedures in which they agree to participate; furthermore, the participants may experience

potential discomfort following the study when they are notified of the deception (Fisher and Fyrberg, 1994; see also Fried, 2012; McCambridge et al., 2013; Sieber, 1982).

The most recent revision of the APA Ethics Code (2010) includes a more protective stance on deception in research, prohibiting the use of deceptive procedures if: (1) effective nondeceptive alternative methods are feasible or (2) the research is reasonably expected to cause participants physical pain or severe emotional distress. The standard also stipulates that researchers must debrief participants about the deception as soon as possible and permit them to withdraw their data following debriefing. For more information on informed consent, *see* Informed Consent of Research Subjects.

Protecting Participant Privacy

Social scientists respect the privacy and dignity of persons by protecting confidential information obtained through the course of research. Standard procedures for protecting confidentiality include use of participant codes on all data-collected materials, keeping password-protected files, limiting access to personally identifiable information to research staff members, and attaining competence in protecting information collected over the Internet, mobile phones, and other new technologies (Fisher, 2013). Investigators must also ensure that recruitment and research procedures do not in themselves inadvertently reveal confidential information. For example, street recruitment for a study on drug use and sexual risk behaviors can inadvertently alert police to the identity of prospective participants who are using or selling illegal drugs (Fisher, 2004). When publishing or otherwise disseminating research findings, investigators need to consider special confidentiality protections when dealing with unnamed but small, unique, or easily identified samples (i.e., participants living on American Indian or Alaskan Native tribal grounds) (Fisher, 2013).

The APA Ethics Code, the British Psychological Association Code of Human Research Ethics, the National Committees for Research Ethics in Norway's Guidelines for Research Ethics in the Social Sciences, Law and the Humanities, and other social science research guidelines recognize instances in which investigators may need to reveal confidential information to protect individuals from harm to themselves or others. For example, a study of school-bullying may reveal that a student is planning to or has already violently attacked another student. Or, during an interview study, a person addicted to drugs comes to the research site in a state suggesting a serious drug overdose. Investigators conducting research on parenting or related behaviors may also be mandated child abuse reporters. Under such conditions, informed consent must alert participants of the investigator's reporting responsibilities if child abuse is mentioned during the course of research interviews or other procedures. Fisher and Goodman (2009) propose taking the following steps in making ethical decisions regarding disclosure of confidential information: (1) anticipate disclosure challenges based on the nature of the sample and data collected; (2) investigate one's own legal responsibilities as well as community resources if an instance emerges in which disclosing information to protect a participant or other is required; (3) based on the above, select a specific disclosure policy before implementing the study; (4) train research staff in reporting procedures; and (5) include a description of the specific disclosure policy in the informed consent. For more information on privacy and confidentiality in research, *see* Privacy of Individuals in Social Research: Confidentiality.

Beneficence

In every research study, there is a continuum of benefits and risks. It is the responsibility of the researcher to maximize benefits, minimize risks, and achieve equitable balance between the two. Consequently, the ethical principle of beneficence is comprised of two complementary actions: beneficence ('to do good') and nonmaleficence ('do no harm'). In applying these principles, investigators are required to maximize research benefits and minimize research risks. Beneficial research outcomes can be achieved directly through clinical trials designed to test the efficacy of an educational, behavioral, or medical intervention, or indirectly through descriptive research identifying the individual, interpersonal, social, economic, or other contexts influencing behavior or health.

Scientific merit is a minimal requirement for determining whether possible research risks to persons or groups are ethically justified, based on the study's proposed scientific validity and value. A poorly designed study holds no possibility of benefits. Research must be designed to produce reliable information according to accepted principles of research. However, a study may be well-designed, but the benefits are not balanced by research risks if the hypotheses themselves do not meaningfully enhance understanding of a social or psychological phenomenon, or help to ameliorate an educational, behavioral, or health-related problem (The Nuremberg Code, 1949). The threshold for scientific validity and social value is higher when research is conducted with vulnerable groups such as social minorities or historically oppressed groups and requires: (1) an awareness of the importance of scientific, social, and political factors governing definitions of race, ethnicity, and culture; (2) an understanding of between- and within-group differences; (3) familiarity with and skills in constructing and implementing culturally valid and language-appropriate assessment instruments; and (4) knowledge of the cultural and political circumstances of participants' lives (Fisher et al., 2002). Social value has gained increased attention as a key requirement for research, and is becoming central to the current revision of CIOMS (Bahn, 2014).

Participant Perspectives

In recent years, there has been a movement to incorporate the views of participant communities in the assessment of research risks and benefits on the assumption that investigators' and RECs' experiences may not be similar to those of participants, and therefore may have different perspectives and perceptions of research harms and benefits (Fisher, 1999, 2011; Fisher and Wallace, 2000). As detailed in several reports by the Nuffield Council on Bioethics, engagement with the community and participants plays an important role in conducting research and forming policy (Nuffield, 2002, 2012).

In both underserved populations in the US and in developing countries, there has also been a movement toward community engaged research (CEnR) (Friedman Ross et al., 2010) that includes community members as equal partners in the development and evaluation of human subjects' protections and research design, implementation, analysis, interpretation, and dissemination. CEnR principles bring mutual respect, community voice, and ways of knowing how to guide research agendas and develop interventions from cultural perspectives that resonate with the study population (Cochran et al., 2008; Minkler and Wallerstein, 2008; see also Alvarez et al., 2006; Boga et al., 2011; Dickert and Sugarman, 2005; Newman et al., 2011; Solomon et al., 2014; Strauss et al., 2001).

Clinical Equipoise

Beneficence also guides investigators in determining whether there is a fair distribution of research risks and benefits in the different conditions to which participants will be randomly assigned in a clinical trial. The effectiveness of a new prevention or treatment study is often evaluated by comparing it to a control condition (i.e., a placebo, treatment as usual). This type of research is often called a randomized clinical trial (RCT) because standards of research design require that participants be randomly assigned to the treatment or control condition. This means that individuals who meet inclusion criteria are assigned to a condition according to chance, rather than by their own choice, or as dictated by the usual response to their diagnosis or prognosis (*see* Placebo-Controlled Trials, Ethics of; Cluster Randomized Trials, Ethical Implications of).

It is unethical to assign subjects to either a treatment or control condition if one of those conditions is known to be inferior. Before beginning a treatment-control group study, the investigator must be honestly able to state that sufficient scientific or clinical evidence does not yet exist to conclude that subjects in the treatment condition will differ in outcome from subjects treated in the control condition. According to the concept of clinical equipoise, a treatment-control group study may be justified where there is a current or likely dispute among experts as to which of the two or more conditions is superior (Freedman, 1987; Weijer and Miller, 2003).

Justice

The principle of justice addresses two primary questions: who should bear the burdens of research, and who should receive the benefits? Another way of thinking about justice is "who is obligated to provide what to whom and why" (Pratt and Loff, 2011, p. 75). The principle of justice has emerged as a moral imperative in human rights debates regarding access to research and the individual and group benefits it may generate. An injustice occurs when disproportionate burden in research is imposed upon a group, population, or individual. For example, this occurs when institutionalized persons are recruited as samples of convenience for studies designed to benefit the larger population. Injustices also occur when specific social groups are excluded from the benefits of research; for example, when studies on educational or mental health interventions are conducted with middle-class ethnic majority participants with the results generalized to services delivered to poorer ethnic minority citizens.

One application of justice is the investigator's responsibility to ensure fair procedures and outcomes in the selection of human research subjects. An ethical issue arises when racial or ethnic minority, disadvantaged, or disenfranchised populations are recruited to participate in studies that do not include consideration of the unique population characteristics that may reduce their ability or capacity to receive the benefits of the research, or expose them to greater risk or financial burden (Fisher, 1999; Trimble and Fisher, 2006). Over the past decades, for example, US federal regulations have been modified to encourage inclusion of social minorities in research, and to require investigators to justify the exclusion of women, ethnic/racial minority groups, or children from research applications for federal funding.

Distributive Justice

In addition to the issues discussed above, there are also issues of distributive justice in research. Who or what should determine the priority and focus of research? In other words, should priority be given to research involving those most in need of improved health (Dresser, 2001)? How should funding agencies decide who is most deserving of their budget? For example, a funding body may have to determine whether to spend money on research on a less serious, but widespread health problem like arthritis, or on studies examining more serious but uncommon conditions. Current debates include whether an 'affirmative action' approach should ever be taken to research funding, and if so, whether current research focus should on populations that were previously excluded from or underrepresented in research (Dresser, 2001).

Justice in International Research

As research becomes more globalized, certain ethical challenges arise that are specific to international and cross-cultural research, particularly in situations where the researcher or funding institution from one country is conducting research in another country. Researchers may decide to conduct research abroad in order to study the behavior a specific population, to help the host country address a public health problem, or because a certain location is a more convenient, efficient, or less troublesome site for conducting a particular clinical trial (NBAC, 2001).

When conducting clinical trials in developing countries, risk – benefit assessment takes on different dimensions, because the access to health care outside of the context of research may be limited (Macklin, 2004). The principle of justice requires an understanding of the health needs and priorities of the host community or country; providing the participants with fair benefits during and after the research (including access to treatments or practices that may have been developed by the study); and strengthening the research capacity and ethical review process in the host communities or countries (Pratt and Loff, 2011). Ensuring that these ethical obligations are met is important in the promotion of

global justice, and to fill research gaps in underperforming countries, and to reduce health disparities between nations (Pratt and Loff, 2011).

In some countries, investigators may need to consider state-sanctioned discrimination or disempowerment of certain groups. For example, traditions in some localities may require an investigator to obtain permission from a woman's husband, father, or other male relative before approaching her for research participation. In such situations, these traditions may be respected, but it is ethically imperative that protections are put in place to ensure that the woman's consent is informed and voluntary (NBAC, 2001; Pratt and Loff, 2011). Moreover, research should never be conducted in communities where political structure or power imbalance based on gender would, in any way, compromise the voluntariness of participation by pressuring women to participate, or when such procedures will justify or defend the violation of human rights (Fisher, 2013). For more information on cross-cultural dimensions of research ethics, *see* Research Ethics, Cross Cultural Dimensions of; Fieldwork: Ethical Aspects; Gender and Social Research.

In international social science research, the researcher and participant communities may have different concepts of physical, informational, and decisional privacy (Goldman and Choy, 2001). These differences can manifest themselves in various ways. For example, in societies with living arrangements and cultural values that emphasize community openness and family independence, participants may question the motives of a researcher who attempts to conduct research interviews in the absence of family members (Monshi and Zieglmayer, 2004). As a result, when conducting international and/or cross-cultural research, it is important for the researcher to determine how the participant population defines and values privacy, and then design confidentiality procedures to reflect these values (Fisher, 2013). In localities affected by war, or in which vulnerable populations such as gay and lesbian individuals or drug users are subject to imprisonment, investigators must ensure that their recruitment procedures do not identify individuals in ways that place them at risk of violence or incarceration (Wolfe and Cohen, 2010).

Conclusion

Over time, there has been a shift in emphasis of the ethical principles of research ethics, from an approach primarily focused on informed consent, to one that incorporates increased consideration to justice. Additionally, increasing numbers of international research studies – a by-product of our ever-globalizing world – brings along with it numerous ethical challenges. It is crucial that researchers see the importance and value of adhering to the aforementioned principles in their work in an effort to maximize the benefits of research for our global society.

Research Funding: Ethical Aspects

Virginie Pirard, Institut Pasteur, Paris, France

This article is a revision of the previous edition article by Ørjar Øyen, volume 19, pp. 13240–13242, © 2001, Elsevier Ltd.

Abstract

Ethical concerns related to the research funding process are usually connected with the question of influence between the funder and the beneficiary. This influence can be clearly demonstrated whether the funder is a profit-seeking company or not. However, because of its possible negative outcomes on paramount ethical values such as freedom of research, distributive justice, and scientists' responsibility toward community needs and goals, this issue should be carefully assessed at every stage of the research process. A crucial way to assess these links is to maximize transparency and to raise both the scientific community and civil society's awareness.

Sources of Ethical Concerns

Ethical concerns occur when some ethical principles might be affected in a given situation. What kind of principles and situations are involved regarding research on the one hand and funding on the other?

Freedom of research appears as one of the most well-known fundamental principles in science because of its crucial link with the claimed goal of Science: seeking truth on the basis of facts.

This 'simple' goal has caused a lot of controversy in the last centuries about the meaning of 'truth,' 'facts,' and more recently, 'objectivity' in science. These debates are beyond the scope of this article. However, it appears that production of a valid scientific knowledge requires strong and defined methodologies, allowing replication of the experiments and verifiability (or falsifiability, following K. Popper's philosophy) of the experiments' conclusions, as well as protection against any undue influence. In that perspective, scientific knowledge is socially considered as objective, even if, from an epistemological point of view, objectivity in research seems more like an ideal than an always-present-reality.

If the pursuit of objectivity in science requires scientific researchers to be free from any undue influence, the funding process can however be a source of influence between the funder and the beneficiary. This is why the funding issue should be carefully assessed at all stages of a research project. Indeed, undue influence could affect the selection of the research area to be investigated as well as the research process itself: methodologies to be used, production of the results, dissemination and exploitation of the results, etc.

Another ethical concern must be considered when discussing the influence of research funding on the selection of the research area to investigate: could influence harm the principle of social and distributive justice which should regulate the allocation of limited resources? This is particularly critical for research related to health, especially when research concerns neglected areas such as rare diseases, pediatric treatments, or health needs in developing countries. Research funding in these areas generates debates on opportunity cost and equality of opportunity for all (Pinxten et al., 2012). It means that when a (public or private) organization decides – or not – to fund a certain type of project, its decision has an impact on the rest of the research funding issues, at least on a theoretical level. In other words, research funding contributes to the establishment of a scale of values which has consequences far beyond the relation between the funder and the beneficiary and leads to maximizing or minimizing existing inequalities in the world. This should be kept in mind by all.

This second ethical concern, less obvious than the first one – freedom of research – leads us to addressing a third point of concern: the responsibility of scientists and funders. The idea of research as an isolated activity, with no link to the actual needs of societies, appears definitely outdated (Marchant and Bird, 2009), even when speaking about basic research. While public funders are more and more inclined to question the social desirability of a proposal before deciding whether they want to fund it or not, private funders are under scrutiny to justify their choice(s) beyond the question of their own interests. Scientists are required to identify and motivate how their project, if funded, would contribute to the progress and well-being of society. This again shows how asking for or granting funding bears responsibility toward community needs.

Outcomes of Influence

Freedom of Research

If funding – whether granted by a public institution or a private organization – seems to generate the possibility of influence between a funder and its beneficiary, this potential influence is particularly problematic when scientific researchers are working on topics connected with general interest (e.g., public health) although their research are, at the same time, funded by a profit-seeking organization or group. Diverging but coexisting interests are mixed in these situations and the capacity of scientists to preserve the objectivity of the research process and the integrity of their research results is questionable. A typical example of this situation is provided when research is funded by gambling, alcohol, or tobacco companies, as recently shown by the addiction industry studies – this new type of studies focused on the relationships that determine policy and regulation in the area of addiction (Adams, 2013).

When Research Is Funded by Companies Which Sell Products with Addiction Potential

These studies reveal some links between scientists and gambling, alcohol, or tobacco companies. These links have the potential to bring an ethical tension between current mixed and diverging interests in research related to addictive products. The sensitive question would then be to determine the nature of these links, and their interactions with scientific objectivity and the stakes relevant for public health.

Of course, the relation between research and addiction companies is paradigmatic of the ethical concern related to research funding because, *in casu*, the discrepancy between the general interest (public health interest) and the for-profit interest is obvious.

Although selling addictive products with potential negative impact on health, private companies aim to show that they care about public health and wish to assume their social responsibility (Babor and Robaina, 2013). This is the reason why they develop 'social aspects/public relation' organizations (SAPROs). These SAPROs, which present themselves as independent and not-for-profit organizations, take part in public debates with policy-makers about public health issues related to tobacco, alcohol, or gambling, and provide limited research project grants to young scientists. Even though they claim themselves as an 'evidence-based organization,' it appears after strong review (Miller et al., 2011), that the research projects funded by SAPROs tend to: (1) deflect attention away from other research areas usually considered as promising on a public health level (Adams, 2013); (2) promote basically only industry-friendly interventions; and (3) avoid to compare, on a scientific basis, these interventions with other actions positively assessed by independent peer-review research. In addition, if it happens that SAPROs are provided with 'nonindustry-friendly' results from a research they funded, evidence is shown that they usually do not refer to these results in their communication campaign.

As a consequence, SAPROs are active in several critical areas for science: sponsorship of scientific research, influence on public perceptions of scientific findings, dissemination of scientific information, and support to public policy actions. However, "case studies and ethical analyses have suggested that active collaboration with the alcohol industry contributes little to the advancement of science or public health" (Babor and Robaina, 2013: p. 211).

This shows the risk for research and scientists when funded by private and profit-seeking companies with interests diverging from the general interest: the potential loss of the capacity to produce 'objective' knowledge. Even if the production of knowledge remains objective, there is a risk of misuse and nondissemination of the research results with consequence on peer-reviewed and evidence-based science as well as for public policies.

Distributive Justice

Funding a research is not an isolated action: it can indeed lead to preoccupation while also contributing to maintaining others silent, given that the funding possibilities are, sadly, limited. Therefore, the question is whether the allocation of these restricted sources takes into account social and distributive justice or contributes to increasing existing inequalities.

When Research Is Funded by Pharmaceutical Industries

Pharmaceutical drugs are supposed to bring at least one of these clearly identified public health's benefits: prevention, relief, cure, or treatment. This should guarantee at least a minimal convergence between the interests involved. In that perspective, the ethical tension observed regarding funding research by addiction companies appears to be lower when pharmaceutical companies are the funders, whether they fund research to develop their own products or are involved in sponsorship activities.

However, pharmaceutical research is currently regulated by the patenting system which "attempts to promote pharmaceutical research by rewarding pharmaceutical companies with market exclusivity for their product. Such a system does not provide enough market incentives to develop innovative, effective, and affordable medicines or health technologies because it focuses on the market competition between pharmaceutical companies on bargaining for global monopolies for their products, (…)" (Oprea et al., 2013: p. 311).

The pharmaceutical research consequently still focuses on 'me-too' medicines (noninnovative drug, similar to an already existing drug, with small health improvements, dedicated to a large population) rather than to take responsibility to create innovative drugs for neglected diseases or for pediatric populations. Even if some major pharmaceutical groups have taken decisive actions to assume their social responsibility and correct that trend, the patent system still contributes to separate the agenda of pharmaceutical research and the public health priorities that replicates and increases inequalities between developed countries and low- and middle-income countries.

This situation has been deeply analyzed by the Consultative Expert Working Group on Research and Development (CEWG) established by WHO in 2010 and a panel of solutions was examined by this Group in order to correct it, at least partially. As this Group showed, this kind of situation also exists when grants are provided by public institutions: "public investment is also dominated by the rich world and its own health needs" (WHO, 2012: p. 1). As a consequence, some research areas are neglected (and not funded) because the definition by the developed countries of public health priorities in the low- and middle-income countries is shaped according to certain perceptions and data: current funding targets research on communicable disease at the expense of noncommunicable disease and other research areas such as resuscitation research (Aufderheide et al., 2013). In that perspective, research funding issues have a political dimension and appear to be connected with responsibility of scientists and science.

Responsibility of Scientists and Science

The idea that the community has ability to hold scientists to account for their research is quite old as Galileo Galilei's case shows it for the worse. In response, the conception of freedom of research and science grew during the seventeenth and eighteenth centuries. This would imply that science should always have sufficient autonomy from any moral, religious, political, or social constraints. However, except for very limited areas of

basic research, the knowledge for its own sake no longer seems relevant. Since many atrocities were carried out in the name of science during the twentieth century – and especially during World War II – the idea that science is always and by itself a factor of progress for humanity is no longer acceptable. In addition to complying with the legal framework, scientists must now justify the interest of their research from a public interest point of view. This trend is clear when observing the criteria used by public organization or agencies to provide funding even when they support fundamental and nonmedical research, as it is the case for the National Science Foundation (NSF). This agency of the U.S. federal government supports fundamental research and education in all nonmedical fields of science and engineering (Davis and Laas, 2013). In its process to grant funding, this agency assesses the kind of 'broader impacts' a research project could bring. By doing this, the funding agency values the advancement of scientific knowledge and activities that contribute to the achievement of societally relevant outcomes. These outcomes may include, among others, the full participation of women; persons with disabilities and underrepresented minorities in science, technology, engineering, and mathematics. Another desirable outcome would be to improve the well-being of individuals in society (NSF, 2013). This criterion also converges with the 'Responsible Research and Innovation' one. Both criteria emphasize the potential desirability of a research for a given society. As a consequence, scientists should not only comply with (1) the respect of national and international regulations, but also (2) the deontological rules of their corporation: they also have to face the ethical necessity to take into account any possible outcome of their planned activity, even if this outcome originates from a nonscientific use of the research results. Due to this evolution, scientists are weighed down by a heavy responsibility – to which scientific studies prepare only poorly, even if there are current debates about how a Scientist's Oath (Revill and Dando, 2006) could be an interesting tool to raise young scientists' awareness of their responsibility. This responsibility concerns as much the risks to avoid as the benefits to expect.

Risks to Avoid – The Example of Dual Use

If scientists are, in principle, trained to take a certain number of precautions when carrying out laboratory/research experiments, things are not as straightforward when considering risks generated by an intentional misuse of a technology or a scientific discovery. The possibility for any knowledge or scientific savvy to be dealt within a dual use must therefore be carefully assessed.

In the United States, the National Science Advisory Board for Biosecurity defined dual-use research as "the development of new technologies and the generation of information with the potential for both benevolent and malevolent purposes" (NSABB, 2007). In Europe, the European Commission chose in 2009 to provide the public with a list of potential dual-use items and defined these as "items, including software and technology, which can be used for both civil and military purposes, and shall include all goods which can be used for both non-explosive uses and assisting anyway in the manufacture of nuclear weapons and other nuclear explosive devices" (Council Regulation (EC) n°428/2009).

The risk of dual use is potentially present in all life sciences research but especially feared in bacteriology and virology research when research experiments could lead to increasing the pathogenicity of viral agents and toxins. The identification and management of this kind of risks require that scientists proceed to a particularly difficult evaluation: beyond their own goal and the scope of their research activities, could their research lead to an additional risk of misuse? In that kind of assessment, also required by the European Commission as Research Funding Agency, scientists have to imagine all the possibilities – even those completely independent of their will and scientific goal – that could lead to a potential misuse such as bioterrorism. Besides the specific difficulty of such evaluation, the scientific community is currently divided on how to deal with a research that could lead to such risks.

While some scientists wish to ban all experiments which could possibly lead to such potential risks (Wain-Hobson, 2013), part of the scientific community considers that these experiments should be conducted if they have a decisive public health interest and if an adequate design and a strong follow-up of this risk during the project's life are provided. While the controversy within scientific community is still ongoing (Casadevall and Shenk, 2012; Webster, 2012), public research funding agencies seem to agree with the later position, at least for the moment. It is worth mentioning that this type of assessment and balance between risk and benefit of research projects with potential dual-use concern is considered as an 'ethical dilemma' by the European Commission. This dilemma requires that scientists should never be left alone with such assessment and responsibility. They must be accompanied by an independent ethics board that could require some specific measures to be taken in order to limit the risk(s): for example, it could recommend the restricted dissemination or even the nonpublication of the research results, which is of course a very difficult situation knowing the existing pressure on scientists to publish their research findings.

The Benefits to Expect – Material and Immaterial Outcomes

As already said, project leaders should be able to anticipate the kind of benefits to expect from a planned project. This requirement seems more adapted to applied science than to basic research. However, the evaluation of the benefits is required even by some agencies (see the example of NSF in the United States) which do fund basic research. The benefits could concern a fully materialized finding (a new technology, a know-how, etc.) or the promotion by and during the research of some socially desirable values.

This points out that, even when research is reputed for being free, knowledge produced by science is not value-free: as noted by Drenth (2006: p. 15), "Scientists cannot avoid the meta-scientific question of whether what they pursue is worth knowing. They have to justify – not only to themselves but also publicly if the taxpayer or a sponsor's money is involved – why scientific issues need to be addressed. In essence, this justification implies non-scientific choices and decisions."

After World War II's atrocious experiments conducted by Nazi doctors on prisoners and detainees, a trial – the Doctors' Trial – was held before the U.S. Military Court in Nuremberg. A part of the sentence given by the law court is well-known as the 'Code of Nuremberg.' This 'Code' sets out the minimal ethical

conditions that any scientific experiment involving human subjects should meet. This list has been adopted and reviewed by several International Ethical Guidelines such as, among others, the WMA Declaration of Helsinki (World Medical Association, Ethical Principles for Medical Research Involving Human Subjects, 1964) and the CIOMS guidelines (Council for International Organizations of Medical Sciences, International Ethical Guidelines for Biomedical Research Involving Human Subject, 1982).

It is interesting to note that, at least since these events, there is an international ethical consensus to consider that a research involving human beings should always prospect to discover new ways of benefiting people's health by improving preventive, diagnostic, or therapeutic interventions. In other words, a research project involving human subjects, conducted for pure scientific sake without any possibility to contribute to these three goals (prevention, diagnostic, treatment) would be unethical. Sometimes, the lessons of history are so strong that no responsible science should ignore them.

How to Deal with Influence: The Ways to Increase Transparency

As previously described, influence is clearly a part of the research funding reality between the provider and the beneficiary. The consequences of this influence may be various for several crucial parameters of the research: from the selection of a scientific question or research area to investigate to the possibility to produce 'objective' knowledge and data, including the way – and sometimes the simple possibility – to disseminate the obtained scientific results. As seen, influence is not systematically a bad thing: indeed, public funders force the scientists who apply to their call to take into account any possible outcome of the research designed in the proposal and, even if it is difficult for the researchers, this is a positive inducement toward a responsible science.

It would however be considered as taking a shortcut to conclude that influence is positive when coming from a public funder, but rather negative when stemming from a profit-seeking organization or company. The issue is complex and no efficient solution can be found if we just look at the source of the funding, although this is of course an important point. In the face of the situation where the influence's paths and nature can vary from one research to the other, all efforts should be made to increase access to information regarding the links between funding providers and beneficiaries. If public funding providers usually require that the scientists disclose the origin of a research funded by them in each paper to publish, things are less clear-cut when the funding providers are for-profit companies. Usually, obscurity is the trend. Following a movement initiated by Ethical Guidelines and, later, by the International Committee of Medical Journal Editors (ICMJE), public authorities in the United States and Europe (see for France, the "LOI n° 2011–12 du 29 décembre 2011 relative au renforcement de la sécurité sanitaire du médicament et des produits de santé") have implemented – or are on the point of doing it – strict regulations increasing the disclosure of links of interests between on the one hand drug manufacturers and, on the other, physicians and researchers.

The Example of the Physician Payment Sunshine Act

Since the beginning of 2013, the rules implemented by the Physician Payment Sunshine Act (2010) have become effective (42CFR parts 402 and 403). This Act sets forth that pharmaceuticals companies, medical device companies, and other manufacturers of medical supplies must collect, gather, and disclose information on any value transfer they provided to physicians when these transfers are over $10 each, or when several payments under $10 to the same physician the same year account for $100 total.

These payments concern, among others, research grants.

The relevant information is to be reported to the Centers for Medicare and Medicaid Service (CMS) which will register, compile, and publish them on a public database by September 2014 (Social Security Administration, 2013).

The obvious goal of this regulation is to increase transparency to the public, a critical point given that data suggest that there is a relation between exposure to pharmaceutical company information – even when this information is claimed as strictly scientific and educational – higher prescribing frequency and higher costs (Spurling et al., 2010). Therefore, what about the influence toward money, gifts, inducements, and grants from these companies when speaking about researchers? As noted by Sismondo (2013), the payments made to researchers are intended to lead medical opinion toward a certain direction, the companies' favorite one. Companies aim to enroll researchers, or at least some of them, especially because they are considered as key opinion leaders (KOLs). Funding their research could contribute to shaping the scientific opinion and, by doing so, to getting influence on other members of the medical community. The tricky point is that this influence is empowered by the reputation of integrity, freedom, and independence of research and scientists, who are supposed to speak only for the sake of science. This situation should not lead to considering that any information provided by a KOL researcher is false or incorrect. However, it underlines how influence plays its game in the process of producing science and medical opinion. This is why some authors call for the 'sequestration' of clinical trial research on drugs or complete separation between pharmaceutical research and marketing unit (Sismondo, 2013: p. 641).

International Ethical Guidelines

Regarding the research involving human subjects, it is interesting to point out that the way of transparency, which a few legislative systems implement and make at present mandatory, was anticipated a long time ago by the International Ethical Guidelines to the research participants' benefit. Indeed, following the WMA Declaration of Helsinki, "each potential subject must be adequately informed of the (…) sources of funding, any possible conflicts of interests, institutional affiliations of the researcher (…)" (WMA Declaration of Helsinki, point 26). Similar requirement is stated in the CIOMS guidelines. Transparency is required in these international guidelines, especially for the research participants. Participants are provided with the relevant information on these issues, and therefore in a position to give their informed consent. Indeed, the disclosure of such information

allows the participants to check if their moral right to choose the kind of research they accepted to support is respected. Participants, yet more than anybody else, have the right to know if private companies will be the sponsor and for which purpose the trial will be held. This may be particularly important for healthy volunteers, who are often driven by altruistic intentions. Their way to conceive their contribution to science could be in complete opposition with some for-profit goals. Transparency should allow these volunteers and any other participants to a research to check if the research project they planned to be involved in is consistent with their moral values.

ICMJE's Recommendations

At the end of the 1970s, a group of editors decided to issue recommendations for the publication of manuscripts in biomedical journals in English. These recommendations, initially focused on formal aspects and standardization, have since been reviewed several times. Issues related to potential conflicts of interest were mentioned for the first time in the 1988 update, in the 'Acknowledgments' section of the recommendations. The recommendation was that "at an appropriate place in the article" should one or more statements specify acknowledgments of financial and material support. The nature of the support and "financial relationships that may pose a conflict of interest" should be specified (ICMJE, 1988).

In the 2004 update, instead of being a part of the Acknowledgments section, the issues related to conflicts of interest were included in the section dedicated to 'Ethical considerations in the conduct and reporting of research.' This section mentioned several rules regarding potential conflict of interest related to project support:

- Researchers should not enter into agreements that could interfere in any ways with their capacity to conduct independently a research and to proceed to its publication.
- The role of the study sponsor(s) should be described at every step of the research process and Editors "may request that authors of a study funded by an agency with a proprietary or financial interests in the outcome sign a statement in which he/she declares that he had full access to all of the data in this study and that he takes complete responsibility for the integrity of the data and the accuracy of the data analysis."
- In addition, Editors should review the protocol and the contracts associated with the research project under review. They may choose not to publish an article if a sponsor has asserted control over the authors' right to publish (ICMJE, 2004).

The updating process of the ICMJE guidelines reveals how the issues related to the conflicts of interest have been regarded by scientific community throughout the last decades. At the beginning, it was considered nearly as an endogamous question, which emphasized the links within the scientific community and considered that these links deserve acknowledgment. Now, the disclosure process of the conflicts of interest enables readers as well as the entire civil society to check how a research project has been funded and conducted from its start to the publication process. Regarding this, it is crystal clear that the ethical concerns related to freedom of research must be shared and managed by both the scientific community and civil society.

Research Publication: Ethical Aspects

Federico Di Trocchio, Università di Roma Sapienza, Roma, Italy

Abstract

Ethical aspects in research publication are all the moral issues and problems raised by any behavioral misuse or abuse of the system for communicating scientific results and information within the international scientific community. Misuses or abuses include plagiarism, self-plagiarism, fraudulent and repetitive publication, unethical or fabricated data publication, censoring negative data, guest-, ghost-, and gift-authorship in multiauthored papers, conflict of interests involving authors, editors, or referees, censoring and rejecting publications on biased judgment, selective reporting, copyright breaches, confidentiality and informed consent infringements.

Such unethical behaviors are tightly related to the misconduct phenomenon, the common origin of both lying on the conflict between the founding ideals of the scientific community and the actual scientific practice, which is far from follow the Merton's norms. Here proposed explanations are discussed as well as ways to prevent or stop the phenomenon.

The intellectual style and the social structure of modern scientific community trace back to sixteenth-century *Respublica litterarum* and eighteenth-century *République des lettres*. This was a virtual supranational community of intellectuals embracing the whole world, all nationalities, all social classes and whose main concern was the advancement of learning. Members conceived of knowledge as 'common property' according to the natural right. Cosmopolitanism, integrity, impartiality, and independence from politics, religion, and economic constraints were its essential and ideal characteristics; so that the republic went eventually to be steadily grounded at least on three of the four Mertonian norms: universalism, communality, and disinterestedness. There was no competition other than for recognition of intellectual excellence and priority.

This was however mainly a literary enterprise and the scientific one was born as a specialized province of it for which M. Polanyi (1962) coined the new sociological concept of 'republic of science.' Specialization was acquired mainly through scientific method by which the ethical norm of organized skepticism was also firmly stated. Scientists developed an explicit conception of experimental procedures, use of controls, repetition of experiments, exhibition of numerical results of actual measurements as well as those calculated from theory, recognition of approximations, and estimations of experimental errors. On this basis scientific knowledge came to be conceived as community property unceasingly increased by individuals or groups in mutual cooperation and fair and honest competition; and researchers are intended as primarily engaged in the disinterested pursuit of truth and in the quest of new insights and discoveries. Honesty toward oneself and toward others is considered as a fundamental condition for cooperation and fair competition, since researchers depend on each other and cannot be successful unless they are able to trust each other and their predecessors.

Crucial was the radical innovation of the communication system. The printed book and scientific correspondence were the essential means of detailed informal exchanges of ideas and information within the republic of letters. Within the republic of science the function of private correspondence was taken over and that of books modified by the professional scientific journal as a medium for reporting experimental research into specific problems. The original and main aim of a scientific paper was to give details of how to repeat experiments (repeatability). Today merely to rediscover the results of already published investigations is considered quite trivial: we mainly rely upon the honesty and competence of the original observers. In other words, the critical role of each scientist with respect to the experimental work of his/her colleagues has been somewhat abrogated but still exists in principle: there is always the likelihood that experiment will be repeated.

To warrant this moral and professional commitment and, at the same time, ensure clarity and quality, the scientific paper has been submitted to the peer review process, and progressively restyled in a standardized format. The process of soliciting peers (experts) to evaluate scholarly work prior to publication was initiated in 1731 by the *Medical essays and observations* of the Royal Society of Edinburgh but became of general use as a full structured practice only in the middle of the twentieth century. In the meantime, the article evolved from the letter form and purely descriptive style in the seventeenth century, to a very standardized structure in four main sections: introduction, methods, results, and discussion (IMRAD format) which began to be used in the 1940s and was adopted as a majority in the 1970s. Publications came to be the primary medium through which scientists give an account of their work, cooperate, contribute to the advancement of knowledge, and claim the rights to be recognized for their discoveries. Therefore, dishonesty in publication not merely throws research open to doubt but destroys the very fundament of science.

On the basis of these ethical and professional premises the scientific enterprise grew up as an effective and reliable system for the advancement of learning from sixteenth to nineteenth century.

Problems began to rise in the 1940s when modern science policy was established in view of the expected contributions of the scientific community to national defense and industrial progress. Paradoxically enough it was in these very years that Merton (1942) delineated the 'ethos of science,' a set of descriptive norms (communism or communality, universalism, disinterestedness, organized skepticism) that govern

scientists' relationship with each other. It has been noted (Macfarlane and Cheng) that in the 1940s as today Merton's norms were anachronistic and no more descriptive of actual scientific practice. It has been even asked if would it not be appropriate for a scientist to promote the norms of capitalism, particularism, and interestedness as key elements during the daily struggle for reputation, funding, and research grants. Especially disinterestedness as a scientific norm loses support and aligning research with funding opportunities has become common. It seems apparent that professionalization, industrial and military involvement, and the emerging of science policy in Western world created a general condition of potential conflict between the actual practice and the founding ideals of the scientific community. Contemporary escalation of misconduct and ensuing infringements of publication ethics are surely to be linked to this conflictual condition.

The new reward and funding system enhanced the traditional competition between scientists and it was then, in 1942, that the sociologist L. Wilson apparently coined the expression 'publish or perish.' It could hardly be said however that in the first 30 years competition did in some way sensibly promote fraudulent behaviors or the pollution of scientific literature. In fact the turning point has been stated in the late 1970s when the social structure of the scientific community underwent some crucial changes due mainly to the exponential increase of the number of people involved in research and the proportional (though not absolute) decreasing rate in assigning funds to research activity. The ensuing economic constraint (upon which the resources poured in by private companies had no or little effect) led to a situation of even stronger competition among scientists for academic rewards, position, or research funds. One crucial decision was that of the adoption of publication as the main performance indicator and of measuring productivity as the number of publications per length of time. The additional tool of citation analysis which was introduced in those very years (Garfield, 1972, 1979) and based on the key concept of 'impact factor' (as the ratio of the number of citations a journal receives to the number of papers published over a particular time period), and then extended to calculate the impact of the work of individuals, groups, or departments generated a race to produce in the shortest possible time the least publishable unit in a journal with the highest impact factor. Currently over 7.1 million researchers in the world compete to have their research published in over 80 000 scientific journals. At the same time the growth of the scientific population implied a statistical decline in ethical standards and in the quality of production. Lotka's law of productivity in fact states that in a certain field half of the scientific literature is produced by a population of the square root ($\sqrt{N}$) of all N scientists and De Solla Price pointed out that the exponential growth of the scientific population implies a proportional increase in the number of scientists able to author professional papers but not important and innovatory articles. From a statistic compiled by the Institute for Scientific Information (ISI) it resulted for example, that 55% of the scientific papers published between 1981 and 1985 in journals indexed by the Institute received no citation at all (Hamilton, 1990), leading some students to draw the conclusion that more than half or perhaps more than three-fourth of the scientific literature is worthless; while others reacted against the notion that most uncited papers are without value. As for the use of citations as a measure of impact and of the quality of a publication it has been questioned whether this may not lead to abuses such as citation cartels and it was estimated by the same ISI that self-citation accounts for between 5 and 20% of all citation.

It is from, or in any case within, those changes that, according to the current views (see, for example, Petersdorf, 1986) the pathological phenomenon arose of scientific misconduct to which the major ethical issues in scientific publishing are tightly related. As a consequence of the analysis of these issues, the evaluation of the frequency and gravity of the transgressions and the discussions on how to manage the problems they pose have been conducted as part of a general study on scientific misconduct.

The publication of a fraudulent article (the very outcome of a scientific fraud consisting in the fabrication, falsification, or in 'cooking' and manipulating statistical data) remains the most serious transgression of ethics of scientific publication and is commonly considered as an essential part of the scientific misconduct as well as plagiarism, the deliberate presentation of another's ideas or texts as one's own. Compared to these, repetitive publications (publishing the same article in different journals), sequential publication (reporting follow-up of the same study with additional subjects but without new results), 'salami slicing' (dividing up different parts of the same study for publication in different journals) and guest- and ghost-authorship (giving or not giving authorship credit to persons who did or did not take part in the research or in drafting or revising the article) are all considered as minor transgressions resulting in a huge amount of unwieldy and polluted literature which distorts the direction of science. In the 1980s it was roughly calculated that flawed papers published on the 5600 scientific journals indexed at the time by the Science Citation Index amounted to about 10 000 each year. It results from the PubMed database that of the 9 398 715 articles published between 1950 and 2004, 596 were retracted, and it has been calculated (Van Noorden, 2011) that in the past decade the number of retractions has shot up 10-fold while the literature has expanded by only 44%. According to a recent analysis (Fang et al., 2012), about 67% of 2047 studies retracted from biomedical and life science journals resulted from scientific misconduct, while about 21% of the retractions were attributed to a scientific error.

This raises the problem of the reliability of the peer review system designed to assess the quality of scientific literature, and that of the fate of the invalid ideas and data generated by fraudulent publication (Friedman, 1990).

Good scientific journals today publish original articles only after they have been examined by competent reviewers for their validity and originality. The system is credited to have greatly contributed to the efficiency and professional organization of the scientific enterprise but since the 1980s it has been severely criticized not only for its enormous costs in time and money but also for the progressive loss of accuracy (Lock, 1986). Reviewers have indeed some moral obligation to make every necessary effort to recognize manipulations and falsifications, but to expect irregularities to be reliably detected would however be misguiding: the original data are not available to reviewers, and if they were they would not have time to

replicate experiments and observations. This is why, according to many, peer review is so vulnerable to dishonest conduct. Other flaws have been detected in negligence (it resulted from inquiries that the higher the academic status and age of the reviewer, the lower the quality of the review), in vested interests of the referees and in many forms of bias (against particular individuals, subjects, or institution) the worst of which is that against the innovatory. Some critics maintain that the peer review system favors mediocre basic science and fails to recognize and promote creativity, originality, and innovation (Horrobin, 1990; Campanario, 1996). Even the anonymity of the referees has been questioned for its finality as contrary to the moral norms of universalism, communality, disinterestedness, and organized skepticism that are thought to characterize the ethic of science. In fact, the peer review system holds some risks for the authors because ideas, research findings, and texts which are unprotected by patents or intellectual property rights are submitted to persons whose identity is unknown to the authors and who may happen to be their direct competitors.

As for the fate of invalid data generated by transgressions to the ethics of scientific communication, the scientific community has yet to agree on the level of inaccuracy required to mandate a retraction versus an erratum or who may retract an article; and though early in 1987 the International Committee of Medical Journal Editors published guidelines for the format and terminology of retraction notices, articles known to be fraudulent may be not retracted at all or retracted with ambiguous retraction while in other cases only part of the data or conclusions are retracted. Editors of journals have little leeway for action since publishing corrections is fraught with juridical risks unless they are jointly signed by all authors. Omitted or ambiguous retraction however are not the only reasons of invalid work not being effectively purged from the scientific literature: it resulted from inquiries on U.S. authors (Pfeifer and Snodgrass, 1990) that after retraction the invalid information they produced continues to be used since the majority of retractions are not indexed by their own journals and no reliable source exists to locate fraudulent or erroneous work.

Some ethical relevance has also the soft censoring activity by which administrations and companies tend to control and restrict the dissemination of sensitive scientific and technological knowledge on the grounds of national security and economic reasons (Relyea, 1994).

Unfortunately, despite increasing publicity during the past 25 years, attempts to assess the quantitative dimensions of the problem of scientific misconduct did not lead to conclusive results: its magnitude is unknown and its detection largely serendipitous. Guidelines and actions adopted to manage scientific and (as a consequence) publication frauds and other abuses vary according to which of the two main different approaches they are based on. Sociologists and the vast majority of scientists share the opinion that the frequency and incidence of misconduct did not sensibly change during the twentieth century and that the impression that fraud has vastly increased may be the result of the heightened self-consciousness in society coupled with strong moral expectation that scientists in the pursuit of reliable knowledge will live up to higher standard of probity. This view seems to be substantiated both by the reports of the two most important U.S. authorities responsible for dealing with misconduct cases, the Office of Inspector General of the National Science Foundation, and the Office of Scientific Integrity of the Public Health Service and by that of analogous authorities in Denmark, Norway, Finland, and Australia. The ensuing suggested strategy is firstly and mainly intended to save the autonomy right and self regulation privilege of the scientific community from legal or government unnecessary intervention, and recommends that inquiries be made primarily by local academic bodies, stressing at the same time the crucial role of education to improve the ethical standards of researchers.

Opposite is the view according to which, though there are no official data on the scale of the problem, the reports suggest that only a comparatively small proportion of cases of misconduct is actually detected and that what emerges is just the tip of an iceberg (Lock, 1993; Fanelli, 2009). According to this view self regulation has proven to be ineffective and unsuitable: scientists are not trained in conflict and conflict of interests resolution; their intuitive response is usually wrong and they tend to set up shaky ad hoc procedures that do not guarantee the accused notice of all the charges, the opportunity to respond to all the charges and to the evidence, and a decision based on rigorous standards. In this view, the setting up of national agencies rather than local committees is recommended and the attention is focused on the economic and social background considering that those transgressions simply reflect the problems of a science which is today too big, too entrepreneurial and too competitive to guarantee its very scope: the cultural and material improvement of mankind, in due and reasonable proportion to the intellectual and economic resources and to a rate comparable to the past one.

As far as scientific publication is concerned this second approach led the Committee on Publication Ethics (COPE), created in 1997 in the UK, to ask for an independent agency to detect, handle, and prevent research publication abuses. COPE provides guidelines and a forum for its member journals (today the great majority) to seek advice from other members on troublesome cases. The establishment of COPE has increased awareness and education but it resulted from a recent analysis of cases managed between 1997 and 2010 (Foo and Wilson, 2012) that the number of ethical cases is not diminishing.

There is however no general agreement on the view which led some of its proponents to recommend for some radical adjustment in the scientific policy, first of all in connection to the ratio between scientific population and funds. While those proposals have been opposed tacitly or patently by universities, scientific societies, funding agencies, and governments, even their advocates acknowledge the importance of improving the ethical standards via the teaching of research ethics which is currently considered by competent institutions and single students besides and before any disciplinary, economic, or legal action. Likewise all agree on the necessity of suitable ethical and professional guidelines and measures which have in fact been proposed or adopted, though independently and according to different experiences and aims, by learning societies, agencies, journals, or individual students.

The primary importance of ethical (coupled with methodological) education emerges particularly in connection to some of the problems of scientific publishing which seem less directly linked to the social and economic structure of the scientific system than to the peculiarity of research areas which involve cultural diversity or human and animal rights. In fact though science is largely transcultural the human community has not yet developed a completely corresponding body of transcultural ethics. In some areas this may affect both methodology and ethics: uncritical and unwitting reliance on the researcher's own culturally received principles and values regarding personal and physical identity, health, loving, suffering, death, etc., may generate potentially distorted initial observations which can lead to systematic divergence from truth in anthropological, psychological, sociological, or medical inquiries (where also systematic infringements of human or animal rights or the exploitation of subjugated populations may occur). Scientific publications based on such inquiries are, in principle, to be considered as poorly or improperly designed and performed studies but current ethical and methodological standards do not include clear and effective rules for authors, editors, and peer-reviewers though the problems they raise have been debated in connection to some controversial cases.

A first general attempt to mitigate the pressure to publish that lies behind most deviant practices is, according to many, to place a ceiling on the number of publications that can be considered in evaluating a candidate for promotion or funding, but some experts have also suggested that the number of scientific journals be drastically reduced (Bracey, 1987). On the same line; although the use of quantitative indicators of scientific performance seems unavoidable, it has been recommended that impact factors shall not by themselves serve as the basis for funding decisions and that the quality of publication must be the primary consideration (Bucholz, 1995). While no effective measures (other than severe sanctions) seem foreseeable against major authorship transgressions, as plagiarism or the publication of fabricated data, it has been recommended to journals to cooperate in cross-checking control activities and to research institutes and universities to store the primary data on which publications are based. All sources and methods used to obtain and analyze those data should be, when required, fully disclosed and the disappearance of primary data from a laboratory considered as an infraction of the basic principles of careful scientific practice. On the other hand, since there is no universally agreed definition of authorship, specific criteria and requirements have been invoked as an acknowledgment or footnote in every coauthored paper to state the exact contribution by each author or the signing of a form where each author affirms having seen the final version and agrees to its publication. According to those proposed criteria the award of authorship should balance intellectual contributions to the conception of studies or experiments, to the generation, analysis, and interpretation of the data, and to prepare the manuscript against the collection of data and other routine work. If there is no task that can reasonably be attributed to a particular individual, then that individual should not be credited with authorship. In principle all authors must take public responsibility for the content of their paper and honorary or guest authorship is in no way acceptable. Against repetitive publication since 1969 the so-called 'Ingelfinger rule' has been proposed (Angell and Kassirer, 1991) according to which papers are submitted to journals with the understanding that they (or their essential part) have been neither published nor submitted elsewhere nor communicated to the media. Reviewers are supposed to vigilate upon transgressions and it is stated in some journals' guidelines that if they suspect misconduct, they should write in confidence to the editor. As for the same reviewers it is reminded that they are bound to the duty of confidentiality in the assessment of a manuscript and asked to disclose conflict of interests and to provide speedy, accurate, courteous, unbiased, and justifiable reports. The submitted manuscript should not be retained or copied and both editors and reviewers should not make any use of the data, arguments, or interpretations, unless they have the authors' permission. Editors should regard their function as ensuring that authors are treated fairly and their decisions to accept or reject a paper for publication should be based only on the paper's importance, originality, and clarity. To avoid the suppression of originality and creativity it has also been recommended that studies that challenge previous work should be given an especially sympathetic hearing and that independent ombudsmen for journals be appointed. Some few suggestions have also been advanced on the subject of external pressures as for example, that editorial decisions must not be influenced by advertising revenue or reprint potential, but it seems that little can be done for the secrecy imposed by industries or governments on sensitive research fields.

Envisaged actions and sanctions rank from a letter of reprimand and warning as to future conduct or publication of a notice of redundant publication or plagiarism, to formal withdrawal or retraction of the paper from the scientific literature, informing other editors and the indexing authorities or reporting the case to the authorities or organizations which can investigate and act with due process.

There is however no suitable insight on the impact those guidelines and measures had or may have in the long term.

Abstract

Residential child care has proved to be one of the most difficult and complex interventions in the lives of children around the globe. There are polarized views about residential care and this is reflected in ambivalence in legislation, policy, and practice. Residential child care, however, continues to have a positive role in the care of children and young people when they are unable to remain in their own families. High-quality and effective residential care should provide an environment that enhances development, promotes resilience, and builds the confidence and self-esteem of children and young people.

Introduction

Residential child care has proved to be one of the most difficult and complex interventions in the lives of children and young people around the globe. It has been used to save and protect children from the consequences of natural disaster, war, disease, and famine. Children have gained respite from abuse and neglect inflicted by their own families. However, residential care has also been used as a weapon of cultural genocide, and it has stripped the children of indigenous peoples of their language, dress, and culture. Children and young people have suffered physical, sexual, and emotional abuse at the hands of carers and other young people. It is not surprising, then, that there are polarized views about the role of residential child care in the range of care services for children and young people and this is reflected in the ambivalence present in legislation, policy, and practice.

In this context, international comparison of policy and practice in residential care is important because it can provide information on the range of problems that is addressed by the use of residential care, as well as highlighting contrasting views of how to respond to particular social challenges. I explore these complex issues in this article, drawing together research and evidence from widely different societies and cultures that can challenge deep-seated assumptions about effective practice with children to find the most effective way to intervene to protect their best interests (Francis et al., 2004).

With increasing globalization and the movement of children across international boundaries as migrants, refugees, and unaccompanied asylum seekers, learning from international comparison becomes important in guiding development in our own countries; highlighting the necessity of dealing effectively with cultural and ethnic diversity (Kendrick, 2008; del Valle and Bravo, 2013).

There are, however, significant issues in carrying out international comparison. Basic information about residential care may be lacking in developing and, indeed, developed countries; and there is certainly a lack of reliable, cross-national statistical information (Francis et al., 2004; del Valle and Bravo, 2013). There are issues of terminology and definition (Ainsworth and Thoburn, 2014). Even basic terms such as 'residential child care' or 'institutional care' are open to debate, and there will be variation in how different forms of care are categorized. A clear example of this is difference in the use of the term 'foster care' in the United States and the United Kingdom. In the United States, 'foster care' includes group homes as well as foster-family care, while in the latter, foster care refers specifically to family care settings and is contrasted with residential care in group settings. The UN Guidelines for Alternative Care for Children provides a useful definition of residential care as:

> … care provided in any nonfamily-based group setting, such as places of safety for emergency care, transit centres in emergency situations, and all other short and long-term residential care facilities, including group homes.
>
> United Nations, 2010; cited in Cantwell et al., 2012.

Residential child care cannot be considered in isolation from its wider context; and countries and localities will have particular economic, political, and cultural histories which affect the legal, policy, and administrative frameworks of child welfare (Courtney and Iwaniec, 2009; Ainsworth and Thoburn, 2014). These will affect the way in which residential care is used, its relationship with other child care services, (such as family-based care), the populations of children and young people placed in care, and specific approaches to care, therapeutic interventions, and practice. Given these issues, practitioners must be at least a little cautious when applying knowledge and practices from other countries to their own residential child care settings.

Despite this complexity and the ambiguity and ambivalence about residential care, there continues to be need for residential child care to meet the needs of particular children and young people, not least because sometimes they themselves have identified their preference for residential care (Kendrick, 2013). This does mean, however, that there is an urgent need to improve standards in residential child care in order to provide high-quality care which will provide a positive and enriching experience for children and young people.

Ambivalence in International Policy

Markedly different experiences of residential child care have resulted in a cross-national ambivalence around residential child care and its role in the continuum of child care services (Anglin and Knorth, 2004; Courtney and Iwaniec, 2009). This

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28077-X

has manifested itself in a range of ways: an unbalanced focus on the negative aspects of residential child care meaning that children can remain in dangerous family situations; the tension between residential care as a 'positive choice' or a 'last resort' and attempts to get rid of residential child care at either local or national level.

It goes without saying that children and young people should grow up in a family environment wherever possible and that this should apply in terms of the child's own family and in the context of foster care and other family-based care. This does not mean, however, that residential care can never be the most appropriate form of care to meet the best interests of the child.

Anglin and Knorth (2004) highlighted how contrasting views have been expressed in the context of two international declarations on residential care. The Malmo Declaration (1986) was drawn up by the European organization FICE (Fédération Internationale des Communautés Educatives). It highlights positive developments in residential care, focusing on new models of 'community' residential care which are treatment-oriented, interdisciplinary, and work in partnership with parents, social networks, and the community. Residential child care is seen not as a last resort but as an important, available intervention. The Malmo Declaration states that residential care should continue to provide a positive environment where children and young people have the opportunity to create their own network of dependable social relationships (Malmö Declaration, 1986, in Anglin and Knorth, 2004).

In contrast, the Stockholm Declaration of 2003, written largely from the perspective of nongovernmental organizations (NGOs) working in developing countries, starts by stating that "[t]here is indisputable evidence that institutional care has negative consequences for both individual children and for society at large" (Stockholm Declaration, 2003, in Anglin and Knorth, 2004). It calls for reduction in the use of residential care in favor of community and family settings, and suggests that residential care should only be used as a last resort. From this perspective, there is a clear suggestion that the ultimate goal would be an end to the practice of placing children in residential care.

Interestingly, the differing contexts of the authors of the two declarations led to markedly different conclusions. These contrasting views highlight the ambivalence about the role of residential child care, which is apparent in policy, practice, and legislation in different national contexts.

UN Guidelines on Alternative Care for Children and Their Implementation

A more balanced approach to the current position of residential child care in the range of options for alternative care for children away from home is in the work that has been done under the auspices of the United Nations. The starting point for this is the 1989 UN Convention on the Rights of the Child (UNCRC) which sets out the basic human rights that children everywhere have: the right to survival; to develop to the fullest; to protection from harmful influences, abuse, and exploitation; and to participate fully in family, cultural, and social life.

Placement of children in out-of-home care is primarily addressed in Article 20 of the UNCRC and it states that children who are deprived of their family environment, or who cannot be allowed to remain there, are entitled to special protection and assistance from the state. They are entitled to alternative care that "could include, *inter alia*, foster placement, kafalah of Islamic law, adoption or if necessary placement in suitable institutions for the care of children" (UNICEF, n.d.: p. 7).

In 2009, the United Nations General Assembly adopted the *Guidelines for the Alternative Care of Children* in order to provide more detailed, internationally recognized guidance and to enhance the implementation of the UNCRC (Cantwell et al., 2012). The 'Guidelines' set out desirable policy and practice approaches to support efforts to keep children in their families and, where this is not possible, to ensure that the best interests of the children are upheld in the provision of alternative care, including residential care. Cantwell et al. (2012) set out three basic levels of preventive action given in the 'Guidelines' which involve: the general population's access to basic services and social justice; targeted support to the families of children at risk; and support for the reintegration of children with their families at the earliest opportunity.

The 'Guidelines' acknowledge that all decisions concerning alternative care should minimize disruption and facilitate reintegration with family. Removal of a child from the care of the family should be seen as a measure of last resort and should be, whenever possible, temporary and of the shortest possible duration. A range of alternative care options should exist and while priority should be given to family and community-based care, placement in residential care should be made where such a setting is specifically appropriate, necessary, and constructive for the individual children concerned and in their best interest.

A number of reasons are identified that can make residential care the best option for children. Negative experiences in family settings can mean that foster care is not the best option for some children and young people. Residential care can also provide the best placement to keep groups of siblings together. It can also provide specialized care and treatment for children who have experienced trauma and abuse. In addition, some children and young people prefer residential care to family-based placements.

The 'Guidelines' outline the requirements for high-quality standards in residential child care. It should be based on 'small-group' living that promotes appropriate relationships between children and carers, taking into account the importance of attachment and supporting relationships with specific carers to children's well-being. While residential care should be seen as a temporary measure with the aim of returning children to their families, it may be required for a longer time for the small number of children who cannot return to their families and for whom foster care or family-based placement is not appropriate. There needs to be a rigorous framework for the regulation, monitoring, and inspection of residential settings. Children's rights need to be protected and these include: participation in decisions affecting them; contact with their parents, wider family, and community; complaints procedures; and the monitoring and review of outcomes. There is also a need for high-quality staff in residential care, with strategies to recruit, select, and accredit carers and provide support and training for them (Cantwell et al., 2012).

'Deinstitutionalization' and the Move Away from Residential Child Care

The Guidelines on Alternative Care of Children also comment on the issue of deinstitutionalization, and this is important in the development of positive approaches to residential child care. Cantwell et al. (2012) point out that in this context, it is important to distinguish between 'residential facilities' and 'institutions,' and it is the latter that need to be targeted through a deinstitutionalization strategy. The issue with such settings is not simply size but rather the nature of the care regime – the institutional culture that depersonalizes and isolates children and young people, and fails to address their individual and emotional needs. van Ijzendoorn et al. (2011) note the following negative characteristics of institutional care:

- Group sizes tend to be larger and the number of children per caregiver is large.
- Groups tend to be homogeneous in terms of age and disability.
- Caregivers for any single child tend to change constantly because of staff turnover, shift patterns, and rotas.
- Other adults tend to come and go in children's lives.
- Caregivers are poorly trained and their work is focused on physically caring for the children.
- Caregiving tasks tend to be carried out with a lack of warmth, sensitivity, or responsiveness.

It is institutions with such harsh regimes and negative outcomes that are the focus of the Stockholm Declaration and they are rightly the focus of the deinstitutionalization agenda.

Where 'institutions' do still exist, the 'Guidelines' stress that alternatives should be developed which will allow for their progressive elimination. This needs a national, strategic plan for deinstitutionalization and the development of a range of alternative services including small-group homes, foster care, support services for parents and extended family, and support for young people to live independently. Planning of alternative services is especially important in addressing the needs of disabled children and those under the age of 3 years.

The process of deinstitutionalization, however, is not an easy one, and there are a range of issues that need be addressed. Negoita (2010), for example, raises serious concerns about the process of deinstitutionalization in Romania and, in particular, the pace of the reform changes driven by a wider political agenda. She argues that although the initial results of the movement of children out of large institutions into the community and to smaller residential homes were considered successful, there were longer-term negative consequences. For example, for many of the children who were returned to their families, there have been continuing issues of lack of support. There have also been major concerns about abuse in foster care and the ramifications that this has had in terms of audit and bureaucracy. Frimpong-Manso (2013) found that there were similar issues in the deinstitutionalization program that was set up in Ghana. While there were promising developments in family- and community-based care, the reform program struggled to achieve its aims. Children returned to families which did not have the resources or support to care for them, and some were at risk of abuse; there was also a lack of financial and human resources to implement the goals of the reforms.

In many countries, large institutional care settings are a thing of the past – the workhouses, orphanages, and industrial schools of nineteenth- and twentieth-century Britain, for example, have long gone, although their shadow still falls on current perceptions of residential child care (Kendrick, 2008). The process of deinstitutionalization in Western Europe, North America, and Australia is linked to the general reduction in the use of residential care. Along with the negative perceptions of institutional care (a focus on poor outcomes and scandals of abuse), there has been a move toward prevention and support in the community, and family-based forms of care. The extent of the reduction and the pace of change, however, have varied a great deal (Kendrick, 2008; Courtney and Iwaniec, 2009; del Valle and Bravo, 2013).

The consequences of deinstitutionalization have perhaps been most striking in Australia where it has been suggested that the scale of the reduction of the residential sector has led to major disadvantages for children and young people (Ainsworth and Hansen, 2005). Driven by the negative impact of experiences of Aboriginal children and child migrants in residential care, along with the financial and ideological drivers that have given priority to foster and family-based care, Australian state governments reduced the use of residential care drastically. Ainsworth and Hansen (2005) highlight, however, that appropriate alternative forms of care have not been developed. They detail how homelessness programs, the juvenile justice system, and foster care have to deal with disturbed and vulnerable children and young people who would be better served in appropriate residential care.

> The dream – no more residential care – has gone disastrously wrong.
> Ainsworth and Hansen, 2005: p. 197

The Use of Residential Child Care

Already in this article, there have been indications of the range of factors that will determine the development and use of residential care in different countries. These will include the complex interplay of historical, economic, political, ideological and cultural factors (Courtney and Iwaniec, 2009; Ainsworth and Thoburn, 2014). This has led to a marked diversity in the use of residential child care across the countries of the world, and there is often rapid change.

Ainsworth and Thoburn (2014) provide an overview of the use of residential child care in 21 countries. First, there are major differences in the rate of children in care in the population. Countries that were part of the former Soviet Union have high rates of children in care (Russian Federation, 305 per 10 000 aged 0–17 years; Lithuania, 246; Ukraine, 194). A cluster of countries have rates between 50 per 10 000 and 80 per 10 000 (Australia, Germany, Ireland, Spain, Sweden, England, Scotland, and the United States). Of the countries included in the study, Japan has the lowest rate of children in care, only 17 per 10 000. There are further significant differences in the proportion of children in care who are placed in residential care. At the extremes, Australia has only 6% of children in care, in residential care, compared with Armenia,

which has over 95% in group care. (Only Australia and Ireland have less than 10% in residential placements.) England, the United States, Hungary, Scotland, Spain, and Sweden have between 10 and 30% in residential placements. France, Romania, Denmark, Italy, Poland, and the Russian Federation have between 30 and 50% in residential care. Germany, Lithuania, Ukraine, Czech Republic, and Israel have between 50 and 80% in residential care. Finally, Japan has 92% of its children in care, in residential placements (Ainsworth and Thoburn, 2014: p. 18).

The Communist states of Eastern Europe evidence the role of political ideology in the development of residential institutions after 1945, and the significant move away from institutional care following the breakup of the old Soviet empire. Economic development and industrialization can create a demand for residential child care because of the breakdown of traditional family and community structures. More recently, however, the impact of recession and financial austerity has placed families under stress and disadvantage, which may lead to abuse, neglect, and the breakup of families. This can also create a need for residential care. In China, the birth planning policy has been linked to the eightfold increase in the number of children in child welfare institutions between 1984 and 2004, although other social and economic factors have undoubtedly contributed (Apter, 2014). The role of religion and religious organizations has also had a major influence in the development of residential care in particular countries. In Ireland, however, a backlash has been seen in the almost entire eradication of residential care due to the scandals of abuse in Catholic residential establishments. Broader cultural norms can affect the balance between residential care and foster care. For example, in Japan, traditional views of the family have led to the marked predominance of residential over foster care.

Major events such as disaster and disease have had a significant impact on the development of residential care in some areas. The largest child welfare problem in many developing countries is that of children who are orphaned (Abebe, 2009). A great deal of the residential child care that exists in some countries caters to children who are in need as a consequence of disease (notably HIV/AIDS), natural disasters such as the South Asian tsunami of 2004, and war. There has been a significant involvement of NGOs in the establishment and delivery of residential provision in Africa. This is mirrored in other parts of the world, particularly in countries such as Cambodia, where political and social upheaval has left a continued legacy of orphaned, abandoned, and vulnerable children (Emond, 2010).

Models of residential care, unsurprisingly, differ widely, from large-scale institutions providing basic care and education for children to specialist, small-scale provision offering therapeutic services. There has been a general tendency for residential homes to become smaller, and, in the United Kingdom, it is not unusual to have homes for three or four children. Indeed, there has been a recent rise in the number of residential settings for individual young people. This involves individual young people being supported by a group of residential staff members and often these placements arise out of crisis situations. In 2013, there were over 100 registered homes with just one place in England (OFSTED, 2013). The significance of this development is the move away from the 'group care' element of residential care.

Although the general trend has been toward smaller residential establishments, there continue to be larger establishments that do not fall into the category of the institutions described above. The campus or village model is found in both the developed and developing world. In the United States, for example, Boys Town has villages across the country. The largest is the Village of Boys Town in Nebraska which is a municipality in its own right – with its own police and fire departments. At any given time, some 550 children and young people live in this village. The Boys Town approach is for an integrated continuum involving community support services; in-home family services; foster family services; treatment family homes; intervention and assessment services; specialized treatment group homes; and intensive residential treatment (Ivey, 2000). Another example of the village model is the SOS Children's Villages movement, with some 500 villages in 124 countries around the globe. Children are placed with permanent resident SOS mothers in 'family groups' within each village (Abebe, 2009).

Effectiveness, Quality, and Standards in Residential Child Care

There continues to be discussion and debate about the effectiveness of residential child care and the outcomes for children and young people. As has been highlighted above, residential child care covers a wide range of settings and environments across different countries. Care is needed in making broad generalizations about the effectiveness of residential care. Adopting a more nuanced approach about what works for children and young people in particular circumstances is necessary. Research has identified that young people often leave residential care and move to independence with poor outcomes (Stein and Munro, 2008). However, this should not necessarily be considered a failure of residential care, but a failure of the child welfare system as a whole. Children and young people are often placed in residential care because of the range and level of their difficulties, either in terms of their behavior or the complexity of their needs, and this has often followed extensive involvement with a range of other services. Research has found that when the complexity of needs is taken into account, residential care is just as effective as other forms of care. Recent research carried out in Cambodia, Ethiopia, India, Kenya, and Tanzania concluded that in terms of health, emotional and cognitive functioning, and physical growth, outcomes were no worse for children based in institutions than those experiencing community living (Whetten et al., 2009). Wolff and Fesseha's (2005) study of Eritrean war orphans compared the outcomes for children in four settings: home-reared children with their own mothers; reunified orphans and their host mothers; orphans in small group homes with their host mothers; and orphans in large institutions. Those placed in smaller group homes had fewer signs and symptoms of emotional distress and greater adaptive skills not only compared with those in institutions, but also compared with those who had been reunified.

Where research has focused specifically on the outcomes of residential child care, it has generally identified positive

outcomes. A review and meta-analysis of the outcomes of residential care for children and youth concluded that, on average, after a period of residential care, children improve in their psychosocial functioning. It found that behavior-modification and family-focused components achieved positive results, as did training focused on social-cognitive and social-emotional skills (Knorth et al., 2008). This is consistent with other research reviews that have identified the positive features of residential care (Clough et al., 2006) and concluded that generally children and young people do better than they were doing beforehand, following a period in residential care (Forrester, 2008).

An important issue affecting children and young people who have been in residential child care concerns their transition out of care back into the family or on to independence. In order to maintain the benefits of time in residential care, it is important that children, young people, and their families have ongoing support. Research has highlighted how crucial it is for young people to have plans in place in terms of accommodation, education or employment, finances, and support networks (Stein and Munro, 2008).

A number of factors have been identified in contributing to high-quality and effective residential child care. The quality of the leadership and management of the homes is crucial and research has highlighted the importance of the role of the manager of the residential establishment (Hicks et al., 2007). The residential home should have clear functions and objectives and the manager of the establishment needs to have a clear philosophy on how the home can meet these objectives. It is also important that the head of the care home has some autonomy in decision making to ensure stability in the running of the home. The manager should have a positive leadership style that is participative, and he or she should work closely, side by side with staff, respecting them and knowing their strengths and vulnerabilities. The manager should also have a good grasp of the specific responsibilities of management, including dealing with crisis situations. Positive leadership and management should enable a strong, supportive staff culture where staff members are agreed on how the establishment should be run and are able to offer consistency in their relationships with children and young people, particularly in the management of behavior. Just as the manager is participative, staff members should focus on the experience of children and young people and spend time with them both individually and in groups. Staff should be committed in supporting children to succeed and developing their emotional resilience and self-esteem.

Children and young people have frequently identified positive relationships with staff members as central to their experiences of residential child care, and the network of relationships is one of the distinctive features of group care. The quality of the interaction between staff members and children and young people in their care is crucial to the success of residential child care. Key features of this interaction should be the staff members' readiness to listen (to the momentous and to the mundane); their readiness to praise success and good behavior; their empathy, approachability, reliability, and persistence. Children and young people can experience such positive relationships as akin to being in their own families. Relationships between staff members and young people, then, are central to defining the residential experience as negative or positive (Kendrick, 2013).

Given the central importance of the quality of staff members in ensuring high standards in residential care and positive outcomes for children and young people, it is of little surprise that high priority should be given to the selection, training and supervision of staff in residential care. In many countries, the education and training of residential care staff has been a neglected area. Even in England, residential care workers require much lower qualifications than social workers, even though it has long been recognized that they are working with some of the most vulnerable and difficult children and young people. In many European countries, people who work in residential child care are social pedagogues; trained to a degree level in the education of children in the broadest sense, promoting well-being through wide-ranging socio-educational approaches (Cameron and Moss, 2007). In North America and some other parts of the world, residential child care falls within the child and youth care profession, which is also a discipline distinct from social work and primarily focused on the growth and development of children and young people in a holistic way, based on direct, day-to-day work with children and young people (Curry et al., 2010). In the United Kingdom, the education and training of residential child care staff is located under the broader umbrella of social work and some have argued that it has suffered because of this (Milligan, 1998).

Key to all training is the focus on relationships, direct work with children and young people in the life-space, supporting the emotional and behavioral development of children, promoting educational achievement (in its widest sense), attachment, and resilience.

Conclusion

This article has aimed to provide an overview of the issues facing residential child care in the context of its diversity and complexity around the world. I have highlighted the continuing ambiguity and ambivalence about the role of residential child care stemming from scandals of abuse and poor experiences of children and young people. However, I have also stressed that residential child care does have a positive place in the continuum of care services for children and young people when, for whatever reason, they are unable to remain in their own family. The future of residential care must be based on the research evidence of what works in achieving positive outcomes for children and young people. There is clear evidence that residential care can be effective in addressing the needs of vulnerable children and young people. The key resources are the staff members who care for children, and it is essential that they receive training and support to engage effectively with children and build positive and nurturing relationships. In this way, children and young people will experience residential care as an environment that enhances development, promotes resilience, and builds confidence and self-esteem.

This article is a revision of the previous article by D.S. Massey, volume 19, pp. 13263–13266, © 2001, Elsevier Ltd.

Abstract

The relationship between racial residential segregation and integration since 1960 has been neither simplistic nor linear, but has actually grown more complex over time. For example, while overall segregation levels have declined since their peak in 1960, progress has slowed significantly since 1980, and the segregation of Latinos and Asians is actually increasing (Rugh and Massey, 2013). Many demographic factors besides race, including nativity, linguistic ability, and socioeconomic status, are critical to the processes that distribute individuals and groups across social and physical space and thus either facilitate or frustrate their upward mobility. It is critical to understand modern dynamics of segregation and integration as they have significant effects on prospects for reducing racial inequality.

Introduction

There is a plethora of evidence that "where we live is consequential for our life chances" (Charles, 2006: p. 4). Inequality in locational attainment, or residential segregation, is a key aspect of and a mechanism that contributes to racial inequality across countless other measures of social welfare (Taeuber and Taeuber, 1965; Massey and Denton, 1985). According to Sampson (2012), our neighborhoods are not just physical places in which social actors react and interact according to regimented social processes, but are actually powerful determinants of those macro- and microlevel social processes in and of themselves. In other words, the spatial is not second to the social; the social is second to the spatial. Therefore the racialized social structure is perhaps best represented by the distribution of racial and ethnic groups across social space, or the phenomenon of racial residential segregation.

One of the first explicit mentions of racial segregation in scholarly literature was by W.E.B. Du Bois, whose landmark work *The Philadelphia Negro* (1899) illustrated how neighborhood racial segregation in turn-of-the-century Philadelphia had critical consequences for the city's Black population. Wirth (1928) and Cox (1948) identified segregation as a primary tool in the maintenance of racial oppression. In their landmark work *American Apartheid*, Massey and Denton explicitly stated that "a racially segregated society cannot be a race-blind society; as long as U.S. cities remain segregated—indeed, hypersegregated—the United States cannot claim to have equalized opportunities for Blacks and whites" (1993: p. 148). The racial segregation of neighborhoods directly leads to the racial segregation of public schools, and schools that have a majority of minorities often suffer from lower quality facilities, less qualified teachers, fewer resources, and lower achievement on tests and grades (Coleman et al., 1966). In fact, racial gaps in educational aspirations, achievement, and attainment persist to this day (Kao and Thompson, 2003).

The relationship between segregation and integration since 1960 has been neither simplistic nor linear, but has actually grown more complex over time. Many demographic factors besides race, including nativity, linguistic ability, and socioeconomic status, are critical to the processes that distribute individuals and groups across social and physical space and thus either broaden or constrain their choices. It is critical to understand modern dynamics of segregation and integration as they have significant effects on prospects for racial inequality.

A Brief History of Racial Residential Segregation in the United States

Somewhat paradoxically, while racial residential segregation became openly entrenched in the American legal system at the turn of the twentieth century, scholarly literature on the subject and public perception of it as a social problem virtually disappeared. National discourse resumed in 1944, when Swedish academic Gunnar Myrdal published *An American Dilemma*, providing an outsider's account of this social problem in the United States. He concluded that residential segregation was widespread, deeply entrenched, and a major barrier to racial equality. Myrdal was also concerned that the phenomenon was self-perpetuating because the racial isolation it produced caused misunderstandings and misperceptions to grow between the races, which, in turn, reified both *de jure* and *de facto* rationales for strict racial separation.

Residential segregation was not truly considered a social problem by the white American political elite until the race riots of the late 1960s saw the nation's ghettos erupt in chaos and frustration. In 1967, President Lyndon Johnson formed a National Advisory Commission on Civil Disorders in order to learn more about the problem and to formulate solutions. In February of 1968, the commission released its report, warning that "our nation is moving toward two societies, one black, one white—separate and unequal" (Kerner et al., 1968).

Coming at a time of confusion, frustration, and fear, the Kerner Report's strong language and bold stance brought popular and prominent attention to residential segregation. Indeed, it was the catalyst for the formulation and passage of the Fair Housing Act later in 1968. The Home Mortgage Disclosure Act of 1975 and the Community Reinvestment Act of 1977 followed, both of which aimed at making sure potential homebuyers of color had access to loans and properties in predominantly white communities. Then, in 1988, the Fair Housing Act was amended, lengthening the

statute of limitations, providing for the payment of legal fees by prevailing plaintiffs, increasing fines for violations, and enlarging the Justice Department's role in prosecution (Massey and Denton, 1993).

Segregation and Integration over the Last 50 Years

In general, at the national level, residential segregation has declined since its peak in 1960. After a brief spike in integration, however, progress slowed significantly between 1980 and 2010. Since 1980, aggregate segregation measures for Blacks have gone down, while Asian and Latino segregation has been on the rise (Rugh and Massey, 2013). Wealthier Asians and Latinos are moving into predominantly neighborhoods, somewhat obscuring the worsening situations of their poorer coethnics (Frey and Farley, 1996). Krysan and Bader (2007) have noted that the 'chain migration' patterns typical for immigrants from Mexico and Central America have made the Latino segregation situation worse than before. Despite these two trends, Blacks always have been and continue to be more segregated than Latinos and Asians, both in the cities and in the suburbs (Massey and Denton, 1989; Charles, 2003).

More has changed in the sociodemographic landscape since the 1960s than these general statistics show. After all, it is important not to think of the American segregation story as linear, moving directly and inexorably total segregation to total integration. First, gentrification and other 'revitalization' efforts have already begun to change cities, especially inner cities, and these areas are often less segregated than others (Frey and Farley, 1996). Gentrification is a controversial endeavor, however, because, while it produces revenue for local economies and encourages multiracial communities, it also destroys existing predominantly Black and Latino neighborhoods, thus displacing those populations of color (Lee et al., 1985).

Another instance of the progressively more complex nature of this story has to do with the emergence of suburbs, or ever-larger rings of residential areas that serve as middle-grounds, even buffers, between city centers and rural areas (Massey and Denton, 1987). Patterns of racial residential segregation are different, not absent, in the suburbs, and not all suburban neighborhoods are created equal (Adelman et al., 2001; Logan et al., 2004). Many scholars have noted that Blacks of higher socioeconomic status are moving from the cities to the suburbs (Alba et al., 1999). These middle-income Blacks live with more whites in the suburbs than they would live with in cities, but they are more likely than suburban whites with the same income to have white neighbors who are less affluent than they are (Alba et al., 2000). Some segregation researchers have documented that crime is on the rise in suburban neighborhoods with higher concentrations of families of color. This leads to white flight, thus racially segregating formerly mixed suburban neighborhoods and concentrating higher rates of crime in neighborhoods in which people of color live (Liska et al., 1998). Other researchers are currently discussing the recent emergence of 'ethnoburbs,' or 'affluent, suburban, ethnic neighborhoods' outside major American cities (Wen et al., 2009).

Suburbs are also becoming the first destinations of immigrants, especially Latino immigrants (Alba et al., 1999). Race, national origin, and English language fluency exert multiple segregative forces on immigrants of color. Foreign-born Latinos and Asians are more segregated from whites than their native-born coethnics are (Iceland and Scopilliti, 2008; Kim and White, 2010). Immigrant families tend to live in neighborhoods of lower quality compared to those of their native-born peers, and their communities tend to experience higher rates of teen pregnancy, higher percentages of students underperforming in school, and higher rates of residents receiving funds from the Aid to Families with Dependent Children (AFDC) program (Rosenbaum and Friedman, 2001).

Zoning, both in the city and the suburbs, has also been a tool for maintaining and increasing racial residential segregation in the post-Civil Rights era. Rothwell and Massey (2009) contend that antidensity zoning in predominantly white areas reduces the availability of affordable, high-quality housing in those areas, thus reducing Black and Latino access to those neighborhoods. Other policies, specifically the trend in subprime mortgage lending among banks in recent years, have also hit families of color particularly hard. More specifically, banks that rated Black homebuyers as risky borrowers because they were purchasing homes in racially segregated neighborhoods penalized them with risky loans, thus putting them in greater jeopardy for astronomical debt and disproportionate rates of foreclosure (Rugh and Massey, 2010). Sharkey (2013) takes a longer view of Black poverty and segregation, describing them as being 'passed down' from one generation to the next. He asserts that it is critical to examine racial inequality in a multigenerational context in order to fully understand its scope, effects, and prospective solutions.

The Consequences of Racial Isolation

Life outcomes for whites in all-white and integrated multiracial neighborhoods are 'statistically indistinguishable' from one another (Cutler and Glaeser, 1997). But vast evidence shows that racial residential segregation has extremely negative outcomes for persons of color. Living in racially segregated and economically vulnerable neighborhoods exposes residents of color to chronic joblessness and underemployment (Santiago and Wilder, 1991; Wilson, 1997); welfare dependency (Massey et al., 1987); low-quality public education (Farley and Taeuber, 1974); more severe and exponentially higher numbers of crimes (Krivo and Peterson, 1996; Liska et al., 1998); and higher rates of asthma, heart disease, and cancer (Waitzman and Smith, 1998; Morello-Frosch and Jesdale, 2006). It is also critical to note that racial residential segregation leads to negative life outcomes, not the reverse, thus debunking cultural explanations for concentrated poverty and segregation (Cutler and Glaeser, 1997).

Explaining the Persistence of Racial Residential Segregation

The question remains as to how segregation has lingered, and sometimes even strengthened, when the practices that facilitate it are illegal and the social acceptance of it has waned. There are three main schools of thought explaining the persistence of

racial residential segregation in the United States. The psychosocial model postulates that individuals want to live near people of their same racial group (Crowder et al., 2006). Evidence from extensive attitudinal surveys suggests that members of all racial minority groups prefer integrated neighborhoods to those dominated by members of their own race. These same surveys, however, indicate that many whites prefer to live exclusively with other whites (Bobo and Zubrinsky, 1996; Charles, 2000, 2006).

The spatial assimilation or socioeconomic model argues that individual gains in education and income enable people to move to higher-quality and less-segregated neighborhoods regardless of their race (Massey and Denton, 1985; South and Crowder, 1997; Crowder et al., 2006). There is substantial evidence in support of this model to explain the residential outcomes of Latinos and Asians, but not those of Blacks; unlike Asians and Latinos, Blacks have a much harder time converting socioeconomic gains into residence in integrated neighborhoods (Massey and Denton, 1987, 1988). And, furthermore, there is significant socioeconomic variation within neighborhoods, regardless of their racial composition (Logan and Alba, 1993; South and Crowder, 1997).

The third explanation for continued racial residential segregation, the place stratification model, attributes more importance to the persistence of racial prejudice in social institutions like real estate agencies, banks, and neighborhood associations (Massey and Denton, 1993; Yinger, 1995). Racist institutional practices such as steering, redlining, and blockbusting actively maintain segregation and constrain the opportunities of Blacks and Latinos to turn their socioeconomic gains into homes in higher-quality neighborhoods (Logan and Alba, 1993). Although this approach takes into account the institutional and prejudicial forces at work in maintaining residential segregation, it has done so at the expense of individual-level factors that are necessary for a thorough and complex explanatory model.

Measuring Segregation and Its Future Study

In 1989, Massey and Denton pioneered the statistical measurement of the concept of 'hypersegregation,' or extreme racial segregation. They sought to compare and contrast the racial residential segregation of Blacks and Latinos in the United States. In order to facilitate this comparison, they identified five dimensions of hypersegregation: (1) evenness, or how uniformly members of a racial minority group are spread across a geographical area relative to whites; (2) exposure, or the degree of contact that members of a racial minority group could have with whites; (3) clustering, or the extent to which neighborhoods with high concentrations of racial minorities are adjacent to other minority-dominated neighborhoods; (4) centralization, or the degree to which minority populations live in and around the centers of urban spaces; and (5) concentration, or the amount of space in a given geographical area occupied by a racial minority group.

The index of dissimilarity, represented by Massey and Denton's measure of evenness, has been and continues to be the most commonly used indicator of segregation. Furthermore, scholars have measured residential segregation using statistical indices of segregation that could be computed for only two groups at a time, usually Blacks and whites. In fact, the vast majority of segregation literature focuses on the Black-White binary. Over the past two decades, however, scholars have begun incorporating Asians and Latinos into their analyses (e.g., Frey and Farley, 1996; Maly, 2005; Charles, 2006). Quantitative researchers have also developed new multigroup indicators of segregation (e.g., Zuberi, 2001; Reardon and Firebaugh, 2002; Iceland, 2004; Reardon and O'Sullivan, 2004), and have pioneered ways of quantifying 'neighborhoods' as units of analysis other than the census tract (e.g., Lee et al., 2008). Still others have been testing new methodologies for studying segregation, including sociodemographic mapping (e.g., Charles, 2006; Frey, 2006; Krysan and Bader, 2009; Pinto-Coelho and Zuberi, n.d.) and qualitative techniques such as ethnography and interviewing (e.g., Maly, 2005). Some scholars are turning their attention to the definition, measurement, and future of stable racial residential integration (Ellen, 2000; Pinto-Coelho and Zuberi, n.d.).

Residential Segregation: Geographic Aspects

Abstract

Residential segregation refers to the practices and ideologies by which socio-economic characteristics are expressed in, and shaped through, the organization of residential space. This article outlines the forces at work in the division of residential space and considers the problem of measuring and interpreting patterns of segregation. It explores the relationship between segregation and inequality, focusing particularly on the ways in which residential has been implicated in both the expression of racism and the articulation of resistance.

Residential segregation refers to the practices and ideologies by which socio-economic characteristics are expressed in, and shaped through, the organization of residential space.

The Division of Residential Space

Residential space is a geographically uneven resource, and the land and housing which constitute it vary in quality, character, condition, and value. Land values vary according to demand and have traditionally been highest in city centres. Housing characteristics vary according to the circumstances of housing production and use, including the macroeconomic climate, the legislative and regulatory framework, the fortunes of the construction industry, the availability of loans and subsidies, changing architectural fashions, and so on.

A primary determinant of access to housing (and neighborhood) is cost, but the markets and institutions that make up the housing system also allow a range of social characteristics to mediate the process of inclusion within, or exclusion from, different parts of the residential environment. It is this interaction of the spatial structure of the housing stock with social structures, property values and with the operation of commercial and public institutions that gives rise to the geography of residential segregation. These processes are, furthermore, embedded in, and legitimized through, the wider set of entitlements, obligations, and ideologies built into the constitutions of states and societies.

Housing and the residential space it comprises is both a commodity and a welfare resource. Housing is bought and sold in the market place, but housing policy can also be a means by which states intervene to meet social needs and alleviate social inequality. Both market forces and governmental priorities therefore play a part in structuring residential space; and such space is fractured in many ways. This fracturing occurs because of differences in 'need' and in 'ability to pay,' and it occurs too because the processes governing access to housing tend to discriminate on the basis of social characteristics. Direct and indirect discrimination has been documented in all sectors of the housing system. In the housing market, access to housing opportunities generally, and to housing finance in particular, may be dictated as much by who people are (or are presumed to be), by what they do, and by where they currently live, as by their actual ability to pay. In the public or social sector, the principle of allocating homes according to 'need' is always hard to operationalize and in practice may be compromised by, for example, subjective discretionary judgments about what types of people 'deserve' what kind of housing, and where.

As a consequence of all this, while class, income, wealth, and other economic indicators provide one set of fault lines in the residential landscape, ideas about 'race,' ethnicity, religion, and language provide another. Health inequalities are also expressed and reproduced in the residential environment; and although most research on segregation refers to the experience of 'households' (implicitly lumping men, women, and children together, and often referring mainly to the experience of men), the division of residential space is also fundamentally gendered and sexualized.

Measurement: the "Index Wars"

A strong empirical tradition underpins the literature on residential segregation, and this has become the province of geographers (*see* Social Geography) and of those whom Peach (1975) terms 'spatial sociologists.' The idea implicit in all this work is that there is some kind of link between society and space; that social processes literally 'take place'; and that where people live is both an expression of who they are and a factor affecting who they can become.

Empirical studies of residential segregation are dogged by the problems of measurement and interpretation. The problem of measurement is apparent from the large literature comprising the so-called index wars. One debate concerns the appropriate index with which to measure segregation. This has revolved around a group of indices of segregation and dissimilarity, which were favored for their simplicity and apparent (though questionable) scale independence. The index of dissimilarity (ID), for example, measures the difference in the distribution of any two population groups over a given number of areal units (e.g., census districts). ID is calculated very simply as half the sum of the difference in the proportion of each group in each areal unit. The index varies from 0 (complete similarity) to 100 (complete segregation) and the value of the index refers to the proportion of either group that would have to move from one areal unit to another in order for the two distributions to be the same.

ID is a special form of the more general index of segregation (IS) which measures the residential dissimilarity of one group from the rest of the population. Several other indices can be

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72118-0

derived from this to capture the spatial segregation and isolation of one or more population groups from one another. Perhaps the best known of these is the asymmetric index of segregation, P*, which describes the spatial isolation of a social group and provides a measure of potential interaction between that group and another (Lieberson and Carter, 1982).

A second point of dispute in the measurement of residential segregation concerns whether the degree of segregation should be gauged against a norm of evenness or randomness. If populations were randomly distributed across space, some clustering would be expected as part of this random pattern. The index of dissimilarity refers to the proportion of a population that would need to move to achieve evenness, and it may therefore exaggerate the amount of segregation that is enforced (or chosen). There is still no consensus on the best way forward here. Nevertheless, all these debates are dwarfed by the problems of how to conceptualize the groups in the study, of whether to standardize (e.g., for income when measuring 'racial' segregation), and, crucially, of how to interpret the results of applying the measures.

Interpretation: the 'Choice-Constraint' Debate

A major debate over the interpretation of measures of residential segregation concerns the question of causality. It hinges around the extent to which people choose to live separately from one another, and the extent to which segregation is forced upon them. This has become known as the 'choice-constraint' debate. In the UK, for example, all the major cities display enduring patterns of residential segregation between the white, African-Caribbean and (South) Asian populations. However, within the Asian populations, Sikhs, Hindus, and Muslims tend to live in different neighborhoods to one another, while West Indians in London are segregated according to the island of origin of those who are migrants. Given these findings, it might plausibly be argued that the residential separation of Hindus and Muslims, or of Jamaicans and Trinidadians, is a matter of choice. Indeed in the USA, Clark (1992) draws on Schelling's (1971) ideas about the aggregate effects of small variations in residential preferences to argue that, in the wake of declining institutional discrimination, the accumulation of own-group residential choices is a key factor sustaining current patterns of segregation in US cities.

While most people do have some choice over the precise space they occupy in the residential environment, the fact that, for the poorest people, these choices are highly limited, leads many authors to focus more on sources of 'constraint' than on elements of 'choice.' Smith (1987, 1989), for example, has argued that while it might well be the case that intragroup segregation is the result of household preferences, it is hard to sustain the argument that a very substantial proportion of such a diverse group as, say, South Asians in Britain, would choose to live in neighborhoods that are on average cheaper, poorer, less well serviced, and more deprived than any others. The demonstrable links between segregation and inequality, the marked extent to which poverty overlaps with (or is constructed through) these spatial processes of marginalization and exclusion, suggests that households segregated into the least desirable residential locations have very little room for maneuver.

Despite a number of conceptual and methodological problems, the empirical tradition has established beyond question that residential segregation is a key feature of the residential landscape, and that, preferences notwithstanding, patterns of residential segregation tend more often than not to be linked systematically with patterns of social inequality (*see* Spatial Equity). Some have suggested that this means that residential segregation has the capacity to act as a catalyst in the process of class formation or as a springboard for collective action more generally. However, in one of the most influential theoretical accounts of the relationships between class structures and residential differentiation, David Harvey (1985) argues that residential segregation is part of the reproduction of social relations within capitalist societies. From this perspective the fracturing of populations into residential communities mainly serves to fragment the class consciousness which might otherwise be used to improve the quality of local life.

Some of these fragmenting, isolating effects of segregation are uncovered by Pratt and Hanson (1994) in a study of women workers in Worcester, Massachusetts. They show how residential neighborhoods are differentiated by the distinctive mix of 'race,' class, gender, and work traditions within them. This mix influences the locational decisions of employers, who work with stereotypes about the differences between men and women's work, and about the suitability of different ethnic groups for particular types of task. Employers' locational strategies thus reinforce a spatial division of labor which already emphasizes the gender divide. But because this division of labor also operates along class and ethnic lines, the potential for solidarity among women is undermined, despite their common interests (*see* Gender and Feminist Studies in Geography). Residential segregation is thus experienced as isolating and exclusionary rather than as a potential resource.

Segregation and Inequality

The literature on residential segregation explores the many social dimensions embedded in the division of residential space. While there is some interest in the location of elites, and in the continuing residential segregation of predominantly "white" ethnic groups (for example Poles, Jews, and Italians in US cities) despite their economic integration, perhaps the bulk of writing focuses on disadvantaged and marginalized minorities. There are therefore studies of residential segregation among people with mental health problems, the old and impoverished, disabled people, single mothers, and so on. However, the main research effort has been concerned with the impact of segregation on the lives of marginalized racialized groups in Western societies (*see* Ethnic Conflict, Geography of). This perhaps reflects the magnitude of the challenge of "otherness" that most developed countries face in a postcolonial world, where 'people of color in the historically white counties of the West are treated as second-class citizens' (Bonilla-Silva, 2000, p. 194). Failure to acknowledge this – that is, failure to recognize the intensely racialized nature of much residential segregation in the Western world – has been criticized by

Wacquant (1997) who (writing with specific reference to the USA) is concerned that by reducing the problem of racial segregation to one of poverty and disadvantage, analysts underestimate the power of history and ideology.

A growing literature on the racial dimension of residential segregation shows that segregation is not just an economic process and a material fact of life, but that it also has powerful ideological underpinnings. Historians George Fredrickson (1981) and John Cell (1982), for example, show that segregation is part of the changing character of racism. The idea of 'race' may have arisen from the notion that particular places (climates and environments) produced different kinds of people ("races"), but the tenacity of this idea is now secured by an unequal distribution of power which allows particular kinds of people to be restricted to particular types of place. Thus racisms become institutionally normalized in and through the spatial configuration of the residential environment (cf Goldberg, 1993).

So, whereas many writers once assumed that racial residential segregation is a declining legacy of a racist, colonial past, Cell and Fredrickson show how segregationism emerged during the early twentieth century as a new and powerful way to manage power relations. In the US South and South Africa, this was initially legally enforced through the Jim Crow laws and apartheid, respectively. But what Cell's analysis vividly shows is that one of the key characteristics of segregationism is its tenacity, flexibility, and ability to survive as a practice even with the declining respectability of racism and even with the end of *de jure* racial separatism. Indeed, Cell goes so far as to define segregation as one of the most successful political ideologies of the twentieth century. 'In a segregated society,' he argues, 'we expect job restrictions and unequal wages; inferior housing, education, transportation, health and social services; prejudiced courts and police forces.' And to the extent that all these forms of exclusion are enacted through the practice of residential differentiation, segregation represents what he calls 'the highest stage of white supremacy.'

Residential Segregation and Racial Inequality

In the USA, the tenacity of these discriminatory and exclusionary forms of segregation has been closely documented by Massey and Denton (1993). Their analysis of the 1990 US census identified 20 metropolitan areas in which racial segregation was so complete and so expressive of the social and financial exclusion of black Americans that they merit the label 'hypersegregated.' Massey and Denton argue for the case of the USA that 'residential segregation lies beyond the ability of any individual to change: it constrains black life chances irrespective of personal traits, individual motivations or private achievements' (1993, pp. 2–3). A startling demonstration of this is given by Polednak (1997) in his study of the relationship between segregation and health which shows, among other things, that mortality rates and infant mortality rates in segregated communities in the USA can exceed those in parts of the less developed world.

In a series of related studies, Massey and colleagues suggest that not only is segregation problematic because it creates spaces of deprivation, exclusion, and neglect, but it is problematic too because the fact of residential segregation acts to concentrate poverty during times of macroeconomic change. So, while all poor people have been affected by those structural changes in the economy which increase income inequality, the most highly segregated communities – in the USA, African Americans – far worst because of the way that residential segregation interacts with economic restructuring to concentrate urban poverty (Massey and Eggers, 1990, Massey et al., 1991).

This work has been contested on both theoretical and methodological grounds by authors who place more emphasis on 'class' than 'race' in explaining recent increases in the spatial concentration of poverty among black Americans. However, Massey and Fisher (2000) have responded with a persuasive empirically-based argument that the same socio-economic changes in a given society have radically different consequences for the concentration of poverty as segregation rises. Residential segregation, they argue, 'is the key factor differentiating the experience of racial and ethnic groups in the United States, dividing them into two basic categories: those whose poor experience a high degree of class isolation in neighborhoods characterized by unusally high concentrations of poverty, and those whose poor do not' (p. 689). Because black Americans are by far the most highly segregated of the studied populations, 'the population of poor experiencing high concentrations of poverty is overwhelmingly black' (p. 689).

This kind of finding is by no means only a feature of societies with a historical legacy of *de jure* segregationism. In Britain, with no history of domestic slavery or legally enforced racial separatism, the residential segregation of racialized minorities has been a persistent theme for more than half a century (Smith, 1989). There has, it is true, been a fierce empirical debate over whether British inner cities are as segregated as many US ghettos. This has centered on whether, for example, an ID of 60 calculated using British enumeration districts is somehow 'better' or less problematic than an ID of 80 for US census districts. However, Smith (1987) argues that while segregation persists at any of these levels, it is the form not the intensity of the phenomenon that is at issue. Whether or not ghettoes are the same thing in all places, that higher levels of segregation are associated with higher rates of poverty, unemployment, poor health, and so on, is indisputable. Indeed, Smith (1989) goes on to argue that segregationism is as effective in Britain as in the USA as an interlocking system of economic institutions, social practices, and political strategies designed by one group to keep another in its place. Residential segregation, then, is a material fact of the lives of marginalized, racialized groups in Britain, and it goes with poor housing, limited employ-
ment prospects, limited service provision, poorer health prospects, and a range of other inbuilt disadvantages,

A key finding in several studies of racial segregation is that, once established, residential segregation is not just an expression of the marginality of racially 'othered' groups, but that it is also a determinant of their future life chances and opportunities. So the iniquitous form that segregation takes not only expresses marginality, but also reinforces it.

This reinforcement takes place in a number of ways. In the USA, for example, it has been suggested that there is a spatial mismatch between those who are unemployed and the jobs they need to survive (*see* Spatial Mismatch). The argument

here is that the spatial restructuring of the economy has taken jobs and incomes away from the areas in which black Americans live (*see* Economic Restructuring: Geographic Aspects). Residential segregation can, in short, act as a constraint on labor market participation. In the UK, a similar process has been observed – there too, entrapment in spaces of deprivation can prevent already disadvantaged groups from seizing opportunities opened up by the restructuring of the economy. In the British example, moreover, this process is overlaid by what might be thought of as a 'welfare mismatch' as those most dependent on welfare find themselves excluded spatially and economically from the range of commodities, insurances, and financial services that have expanded with the 'rolling back' of the welfare state (Smith, 1989).

So residential segregation both expresses social inequalities, and materially affects the participation of spatially excluded groups in social, political, and economic life. But because of its ideological dimension (noted above) segregation is not just a material fact, it is also a political idea – and one which often bears little resemblance to the lived experience of those it refers to. Smith (1988, 1993), for example, shows how, in Britain, 'racial segregation' as a political construction has helped sustain common-sense assumptions about the natural origins of racial differentiation without tackling the problems of racism and discrimination which underpin the inequalities embedded in the structure of residential space. The importance of ideas and images (ideologies) about residential space as a factor structuring people's life chances and opportunities is further illustrated by Anderson (1991) in her work on Canadian constructions of Chinatown. She shows how that segregated space known as 'Chinatown' grew out of, and came to structure, a politically divisive system of racial discourse that justified domination over people of Chinese origin in late nineteenth-century Vancouver. In a similar vein, Wilson (1996) illuminates the power of metaphor to drive the process of uneven development between segregated segments of urban Indianapolis in the USA. His aim is to illustrate what potent political instruments metaphorical symbols can be. In the example of Indianapolis, USA, 'they injected a constellation of representations into everyday thought that rendered a form of growth as value-free and neutral that was, in fact, directly adverse to the interests of the black inner city poor' (p. 96).

Because of its ideological underpinnings and material effects, residential segregation is something that those who are marginalized and excluded by it can have little control over. However, iniquitous forms and practices of segregation can be, and are being, resisted in a number of ways. There is a policy dimension to this, of course, the relevance of which is firmly established by Bashi and Hughes (1997). In a thoughtful account of the likely implications of globalization for the character and intensity of residential segregation by race they argue that the main problems and their likely solutions are located locally (nationally) rather than globally. 'On the topic of segregation,' they note, 'the real problem is less one of sustained explanation than one of sustained action' (p. 120). This adds new significance to the work of those who argue that the best weapon with which to tackle segregation is the law (Goering, 1986, McGrew, 1997).

Other ways of illuminating and challenging the inequalities embedded in residential segregation range from urban unrest to artistic expression. The first of these is extensively documented. The second is less fully recognized, though a glance at the work of artists like photographer Ingrid Pollard, painter Jean-Michel Basquiat, or filmmaker Spike Lee soon illustrates its potency. Ingrid Pollard's exhibition 'Pastoral Interludes,' for example, locates a series of 'black' figures in the 'white' English countryside. This contrasts with the 'usual' positioning of black Britons within the segregated inner city, and challenges the taken-for-granted assumption that it is somehow normal for black people to be absent from rural areas. The other side of the coin – a stark vision of (and dissatisfaction with) the experiences of confinement within residentially segregated urban spaces – finds expression in the stick-like black figures which characterize so many of Basquiat's paintings and in the rise of rap and hip-hop which was used so effectively in Spike Lee's *Do the Right Thing* to speak about life in the segregated space of New York's Brooklyn.

Overview

To summarize, residential segregation is both an expression and a mediation of the ideologies and practices which structure social life. It is a product of the uneven development of residential space and of the selective operation of the markets and institutions that govern access to housing. Residential space is a gateway to services, educational, and employment opportunities, health, and social services. Where people live is therefore a reflection of who they are, but it is also an influence on who they can become. It has therefore been argued that tackling the inequalities embedded in residential segregation is a key priority for public policy and an urgent focus for social concern.

Residential Segregation: Recent Trends

William AV Clark, University of California, Los Angeles, CA, USA

Abstract

Residential segregation continues to be an important topic of research within studies of the spatial structure of metropolitan areas. Although segregation has declined from the high levels of the 1960s and 1970s, considerable racial and ethnic segregation in US and European cities remains, especially, in large metropolitan areas. New methods of measuring spatial segregation are being developed, and a more nuanced approach to understanding the reasons behind continuing residential segregation is emerging. Once, discrimination was invoked as the primary explanation for continuing separation in the residential mosaic, but now most studies emphasize that the explanation is more likely to be a result of the combined effect of incomes, resources, and preferences. Varying combinations of access to resources, preferences for varying proportions of other races and ethnicities, and the urban structure underpin the continuing patterns of spatial separation. Models using agent-based formulations have expanded understanding of how segregation occurs and why it continues in an era of increasing tolerance.

Introduction

Immigration from the Middle East, North Africa, Mexico, and Central America has transformed the urban structure of cities in Europe and North America, and immigration from Asia has had similar impacts in Australia and New Zealand. An outcome of these flows is the emergence of strong ethnic groupings, an outcome that is nearly universal across large metropolitan areas in all these countries. In this context there has been renewed interest in residential segregation, in both its measurement and interpretation. Whereas two or three decades ago concern focused on how to adequately measure residential segregation and whether income and resources mattered in explaining patterns of segregation, now there are real advances in both the measurement and interpretation of segregation. That is not to say that there is universal agreement about how segregation is created or of the relative roles of income, resources, and preferences in shaping observed patterns of segregation; measurement problems also remain. Still, scholars have moved beyond the simplistic argument that discrimination alone accounts for the ethnic and racial patterns so evident in the global city. Now the focus is on building interpretive models of segregation formation and measuring the relative roles of inequality and poverty as fundamental forces underpinning patterns of segregation.

This extension of the first International Encyclopedia of Social and Behavioral Sciences (IESBS) edition entry on residential segregation (reprinted in this edition) focuses on recent trends and takes up five topics central to recent studies of segregation – (1) what are the current trends in patterns of segregation, (2) what are the implications of mixed-race and multiethnic households for the patterns of segregation, (3) how has agent-based modeling improved our understanding of segregation patterns, (4) what do new methods of measuring segregation tell us, and (5) how are changing patterns of segregation by class changing the way we think about segregation.

Measuring Segregation Patterns

How do we know if, when, and where segregation exists? That simple question has created an extensive literature on various indices of segregation and launched a debate about which index to use and which ethnic and or racial groups to include. The residential segregation entry in the first edition of this encyclopedia referred to the 'index wars' as competing groups claimed status for their approaches. Nevertheless, two indices continue to dominate the evaluation of separation in the residential fabric – the dissimilarity index and the exposure index. (Dissimilarity is the proportion of one of any two groups that would need to move in order to create a uniform distribution of the population. Exposure is the probability that a member of one group would meet or interact with a member of another group. See the Residential Segregation entry in the IESBS first edition for formal definitions.) These measures are single indices and use some form of administrative areal unit – for example, blocks, tracts, cities, or counties. Of course the size of spatial unit influences the statistical outcome: the index will be higher with smaller geographic units. In addition, different spatial units in different contexts make comparability problematic.

The dissimilarity and exposure indices both have serious weaknesses; each creates a single summary measure for the metropolitan area, city, or county being examined; and each lacks an adequate theoretical basis. For example, what is the theoretical justification for expecting a totally mixed population of any kind (the definition of the absence of segregation)? Or for an index that requires half the population of one group to move to create an even (unsegregated) distribution of the population across whatever spatial unit is selected? Even the generalized multiple group versions of the dissimilarity and exposure indices still present single measures for metropolitan and regional units. Most critically, neither dissimilarity nor exposure index captures the spatial nature of segregation. This article will later describe recently developed, more sophisticated measures of spatial segregation.

Patterns and Change in Segregation

Residential segregation refers to the spatial distribution of different population groups across neighborhoods and

communities within cities. The 2010 US Census provided support for the continuing decline in segregation levels overall (Scommegna, 2011) as well as in Black–White segregation though some authors have interpreted the new data to show little change. As expected, the changes in segregation vary by ethnic group and by metropolitan area. Overall, America's neighborhoods continue to be segregated, with Hispanic and Asian populations as segregated today as they were 30 years ago although they are much less segregated than are African-Americans (Logan and Stults, 2011).

The 2010 census data analyzed by Logan and Stults shows that the average non-Hispanic White person continues to live in a neighborhood that is quite different racially from the neighborhoods where the average Black, Hispanic, or Asian person lives. Thus, despite a substantial shift of minorities from city to suburbs and despite continued mixing in city neighborhoods, minority populations are still not relatively well integrated in metropolitan American communities. Using binary measures, the dissimilarity index and the exposure index, research by Logan and others shows that Whites still live in neighborhoods with low minority representation whereas Blacks and Hispanics live in neighborhoods with high minority representation and relatively few White neighbors. Still, Black–White segregation trends as measured by the dissimilarity index have declined from a peak in the 1960s of close to 0.82 to around 0.62 in 2010. At the same time exposure has declined much less. To some extent the interpretation is in the context of a glass half full or half empty (I use measures in the range 0 (least segregated) to 1.00 (most segregated) although they can also be reported as percentage values between 0 and 100). Do we focus on the gains or on the continuing relatively high levels of separation? Clearly, change has occurred, but that change has been slower than that expected from the initial desegregation in the 1980s and 1990s (Logan and Stults, 2011).

Is Segregation Over?

Changes in segregation have generated a spirited debate about whether or not 'the segregated century has ended' (Glaeser and Vigdor, 2012). These authors use the dissimilarity index to suggest that the national level of segregation has declined, from about 0.80 in 1980 to approximately 0.55 in 2010. They conclude that American cities are now more integrated than they have been since 1910 and that all-White neighborhoods are effectively extinct. Not only do they argue that in general segregation has declined, especially in the first decade of the twenty-first century; they also document that the separation of Blacks from individuals of other races has declined in all 85 of the largest US metropolitan areas. In the housing markets tracked by the US Census Bureau, segregation is now lower than the average level segregation in 1970.

The explanation for this significant change, they suggest, is changes in federal housing policy that have shifted from actions promoting or perpetuating segregation to actions that diminish segregation. Fair housing legislation as part of the Civil Rights legislation of the 1960s and 1970s affected the ability of minority households to buy and rent housing; additionally, the demolition of large-scale housing projects in major cities increased the long process of population shifts away from inner city 'ghetto' neighborhoods. Also documented has been a change in White attitudes and increased tolerance in society as a whole (Goldman, 2012). The combination of policy changes and attitudinal changes has gone a long way to altering the playing field in which minority households seek housing. Increases in mortgage availability, in Black incomes, and in the number of African-American professionals have influenced the housing opportunity matrix. Still as noted later, the post-2008 housing crisis may have hurt as much as helped Black households.

While the Glaeser and Vigdor (2012) report provides a persuasive case for the end of the segregated century, questions remain about how far segregation has declined and whether the report adequately measures the change in segregation. Using the New York metropolitan region as an example, Alba and Romalewski (2013) suggest that a more nuanced story can be told about segregation and its changes in the past decade. Whereas neighborhoods with mixed ethnic and racial combinations are certainly more numerous, Alba and Romalewski point out that substantially Black, Hispanic, White, and Asian neighborhoods remain in the New York metropolitan region and have changed little between 2000 and 2010. But is New York a special case, and are the measures that Glaeser and Vigdor use comparable to other analyses of segregation?

First, it does appear that large cities that attract large numbers of immigrants are likely to have somewhat higher levels of segregation. This outcome, however, is likely the result of the surge in new – especially Hispanic – immigration to Los Angeles, New York, Chicago, Boston, and other large cities during the 1990s. These new immigration concentrations have been well documented and are often strongly homogeneous clusters of people with similar ethnic backgrounds. That said, increasing evidence shows that these groups are becoming less segregated as their income and resources increase (Clark and Blue, 2004).

Second, unlike most previous studies of segregation, which used the dissimilarity index between non-Hispanic Whites and non-Hispanic Blacks, Glaeser, and Vigdor use non-Hispanic Black against *all* other races which is a measure of separation that differs from that used by Logan and Stults (2011), Farley and Frey (1994) and other analysts. To illustrate the potential difficulty with defining populations differently in the dissimilarity index, I simply note, following Alba and Romalewski (2013), that aggregating Hispanics, non-Hispanic Whites, Asians, and 'other' races, and measuring the relationship with non-Hispanic Black populations confuses the situation in regions and cities where there are large Black and Hispanic populations who are living in more integrated settings. For example in Los Angeles the dissimilarity index is 0.54 in the Glaeser–Vigdor measure while the Logan–Stults calculation is 0.65. In fact for nine of the ten largest cities the Glaeser measure is significantly lower than it is in those studies that use the standard dissimilarity measure based on non-Hispanic Whites and non-Hispanic Blacks.

The continuing debate about levels of segregation between two groups misses the most significant and continuing change in American metropolitan areas: the emergence of substantial mixed-race neighborhoods and increasing diversity more generally.

Mixed-Race, Multiethnic Households, and Diversity

The shift from a majority White population to a population that will be proportionately majority-minority will occur in the US sometime about midcentury. This shift, sometimes called the third demographic transition, of continuing new immigration, high minority fertility, and an overall decrease in the White population has far-ranging implications for measuring segregation. Overall, the US will change from a low-fertility, native-born majority population to a relatively high-fertility, racial, and ethnic immigrant, or children of immigrants, population. This change, as Lichter (2013) has documented, is occurring first and foremost in the children and youth of the US population – diversity from the bottom up. While Whites are still a majority of the older age cohorts in the United States, they are already a minority population among children and younger age cohorts.

It is immigration that is changing diversity and its patterns. Flows of immigrants have integrated and changed formerly minority and White neighborhoods to mixed neighborhoods of White, Hispanic, Asian, and Black. More Americans today, compared to their parents' generation, live in places where Whites, Hispanics, or Blacks represent a modest majority and two or three other groups each enjoy significant presence (Lee et al., 2012).

Another window on changing patterns of diversity comes from the growing number of mixed-race persons (persons reporting that they are multiethnic) and the increase in number of interrace and interethnic marriages (Ellis et al., 2007). An aggregate study of more than 300 metropolitan US areas reported that mixed-race individuals were more likely to live in integrated neighborhoods. The average neighborhood for a mixed-White/Black person is 61% White and 19% Black while the average neighborhood for a person who identifies as Black-alone is only 29% White and 54% Black. The average neighborhood for a person who identifies as White-alone is majority White and only modestly Black. These findings are consistent with a general trend to greater ethnic mixing, and Fasenfest et al. (2004) show that both Whites and Blacks are increasingly living among people of other ethnicities and not just with each other.

A central element of understanding the new patterns is to recognize that minorities, including new immigrants, translate their economic gains into residential movements away from concentrated racial or ethnic neighborhoods as immigrant groups did in previous decades. South and Crowder (1998), for example, show that both Blacks and Whites attempt to convert socioeconomic resources, such as income and education, into residence in whiter and ostensibly, higher status neighborhoods. If, as recent research has suggested, in fact multirace households are likely to be younger, have higher educational levels, and higher earnings levels, then one could hypothesize that these households are more likely to live in integrated settings and will ultimately change patterns of separation in the urban fabric.

Explaining Continuing Segregation

During the 1980s and 1990s, the primary explanation offered for continuing segregation was discriminatory behavior on the part of Whites. Indeed, some sociologists argued that the actions of Whites alone created the segregation of Blacks from Whites: "high levels of racial segregation in the contemporary United States … cannot be explained away by Black and White income differences or… by a resort to notions of personal choice … residential segregation is the direct and continuing *result* of racism" (Denton, 1996: pp. 811, 905). Similarly, a review of residential segregation patterns in a National Academy of Sciences report concluded that extreme geographic segregation is largely unrelated to economic status (and) is not explained by residential preferences (National Research Council, 2001). For much of the past three decades discrimination has been the accepted explanation for residential segregation among Black and White households with similar observable household characteristics (Dawkins, 2004).

But high and growing levels of segregation between Whites and Hispanics, between Asians and Blacks, and between Hispanics and Blacks raised the question of how discrimination was relevant for groups who were newly arrived in the United States and who were living in concentrated ethnic and racial clusters. Was such racial/ethnic clustering created by discrimination or by ethnic preferences and in-group selection? These questions are still being debated, but it is increasingly clear that ethnic preferences and socioeconomic status do play roles in creating residential separation. Several studies have shown that socioeconomic status is relevant in the shifting patterns of separation (Clark and Blue, 2004; South et al., 2005; Quillian, 2002). Research on five gateway immigrant cities suggests that segregation does decline by education as well as by income, though more for the former than for the latter (Clark and Blue, 2004). Indeed, in the inner cities of Miami and New York, segregation does not decline by income, which demonstrates that the picture is at the very least complicated and varies by region and city context.

Still, Iceland et al. (2005) come down on the side of race while conceding that class deserves increasing attention (p. 264). Along with many recent commentators, they are more nuanced in their interpretations and agree that higher status African-Americans generally live in more integrated neighborhoods. Discriminatory lending practices by banks were widely cited as a powerful force in the creation of segregated residential patterns, but such practices are not especially useful in explaining concentrations of gated Black communities in Atlanta or concentrations of wealthy Koreans and Chinese in the suburbs of Los Angeles. Altogether, research now recognizes that money does matter as we will show in the discussion of inequality later in this article.

With respect to preferences and choice – the other area of research on explanations for residential segregation – a specific study of expressed preference showed how preferences can play a powerful role in the choices that households make and in the resulting patterning in the residential fabric (Clark, 1992). These and more recent studies draw on the work of Thomas Schelling (1971), whose influential paper, *Dynamic Models of Segregation*, sought to explain why groups clustered together, whether in the lecture hall or in residential neighborhoods. Schelling argued that small differences in the 'preference' of an individual to be with others of a similar type (ethnicity, for

example) could lead to quite distinct patterns of separation in the population. The paper drew on the individual preferences tradition in economics to show how microlevel voluntary choices and economic competition can create or maintain macrolevel patterns of residential segregation along ethnic and socioeconomic dimensions.

A body of research has since shown that in general significant differences exist among the preferences of Whites, Blacks, Hispanics, and Asians (Clark, 2002, 2009; Clark and Fossett, 2008; Farley and Krysan, 2002; Fossett, 2006). The preferences of Black and White households do differ: in general, African-American households express a stronger desire than do White households to be in a mixed neighborhood. Groups other than Whites also expressed strong own race-ethnicity preferences (Clark, 2009); Hispanics and Asians routinely state preferences for neighborhoods in which they are a majority presence. How should we interpret this outcome of stated preferences? On the one hand, Charles (2000) interprets this finding as revealing not neutral ethnocentrism but negative stereotyping of 'other' races and ethnicities by Whites. On the other hand, Clark (2009) and Fossett (2006) emphasize the role of social distance and neutral ethnocentrism.

The work on agent-based modeling of segregation provides strong support for the Schelling finding that a small difference in preferences for one location or another, or one group or another, can lead to quite strong patterns of segregation and separation (Zhang, 2004; Fossett, 2006; Clark and Fossett, 2008). An important finding by Zhang (2004) shows how separation (segregation) can develop without discriminatory processes. In fact the theoretical work suggests that segregation will emerge from the behavior implied in the Schelling model, even if all parties desired integration. The conclusion that separation can exist across neighborhoods even if people prefer integrated neighborhoods is a fundamental finding because it explains continuing separation in a world of increasing tolerance and a world where opportunities are greater than in previous periods when discriminatory behavior was enshrined in policy.

The research using agent-based modeling has drawn discussions of the distributional forms of the preference function, the nature of the neighborhood, and the role of selection (Bruch and Mare, 2006; Van Rijt et al., 2009). Clearly, it is theoretically possible for the form of the preference function in agent models to influence the outcome with respect to the level of segregation. While some of the debate has been about linear versus threshold functions, it appears that evidence supports Schelling's views. Van Rijt et al. (2009) in fact argue that if anything Schelling understated the tendency to segregation.

Current discussions accept that residential segregation is not the outcome solely of income, affordability, social status, or preferences; it is the outcome of a mixture of these factors tempered by the myriad daily decisions in the rental and owner markets of American cities (Clark, 2002). As has been stated elsewhere, to assert that income does not explain residential segregation is only to assert the obvious: No one factor explains the complex residential patterns so evident in our metropolitan areas, and while discrimination may still play a role in some cases, blaming discriminatory behavior alone is simply not supportable by the research evidence.

Spatial Measures of Segregation

The sociological and geographical communities interested in the spatial structure of segregation have proposed a variety of solutions to the aspatial nature of segregation measures. Wong (2005), Getis and Ord (1992), and Matthews and Yang (2012) have tested alternative ways of bringing a formal spatial function into the measurement of segregation. Each entails innovative thinking about how to measure spatial patterning in the urban fabric. Much of the work builds on research involving a spatially weighted matrix to reflect the extent of contact between spatial units (Getis and Ord, 1992). The most sophisticated of these attempts, uses a spatially weighted matrix to create a modified dissimilarity or exposure index (Wong, 2005); but despite their improved representation of spatial structure, these spatial measures – perhaps because of their complexity – have not supplanted the general use of the simpler, aspatial dissimilarity, or exposure measures.

More recent work aims to generate measures that are truly spatial in that they represent the underlying spatial patterns of the groups being studied and can provide both indices and spatial representations of the underlying patterns. In many ways these new measures build on the ideas of earlier studies that tried to bring distance into the index function. A recent model uses distance and density to generate a mapping of the amount of separation between racial groups. The technique involves computing a measure of segregation at various scales when the scales are defined by local distance radii. Considering increasing radii of 500–4000 m and within each specified radius computing a spatial information theory index comes closer to providing a spatial measure of segregation (Reardon et al., 2008). The index is based on a distance decay function that weights nearby locations more heavily than more distant locations in computing the racial composition in each local environment. Using this tool, one can map levels of segregation, a marked advance over previous attempts at spatial measures of segregation.

A perhaps simpler and more intuitive spatial measure has been proposed that counts 'nearest neighbors' who are similar to or different from the selected respondent. In this scenario a set of differing nearest neighbors – 100, 1000, 10 000 – are examined to see how many are of the same ethnicity, same income group, or some other measurable characteristic. This formulation and the associated methodology overcome the scale problem (the dependence of the segregation index on size of administrative units) and provide measures of separation that focus on the probability of contact with like persons across a set of nearest neighbor distances. Specifically, the technique asks, what is the probability of an individual of one group meeting individuals from a different group (Östh et al., 2013)? The ability to provide a visual picture of segregation, which the Reardon et al. (2008) index also does, is a real advance in incorporating spatial pattern in segregation measures.

Race, Class, and the Changing Urban Mosaic

While ethnic and racial segregation has declined modestly over the past three decades, segregation based on family

income has increased during the same period. In 2010 approximately 28% of low-income households were located in mostly lower income census tracts, an increase from 23% in 1980 (Taylor and Fry, 2012). Over the same time period upper income households became far more likely to live in an upper income census tract (Reardon and Bischoff, 2011). This increase in income segregation is related to the long-term rise in national income inequality, including a decline in the number of middle-class or mixed-income neighborhoods.

Studies from the 2010 Census conclude that mixed-income neighborhoods have become less prevalent whereas affluent and poor neighborhoods have become more common, with the result that the residential isolation of both poor and affluent families has increased over the last four decades (Reardon and Bischoff, 2011). The proportion of families living in poor or affluent neighborhoods doubled from 15 to 31% while the proportion of families living in middle-income neighborhoods declined. The interest in income segregation arises from the argument that neighborhood context can directly affect a person's social, economic, or physical outcomes.

Observations and Conclusions

Understanding of the patterns and causes of segregation has grown significantly in the past two decades. We have a more balanced view of what drives segregation – a combination of income differences, varying resources and preferences, although we also know that private discriminatory practices still occur. Better tools have also emerged to measure the extent and patterns of segregation although the dissimilarity and exposure indices still hold considerable sway.

While the study of ethnic segregation is still important, interest has increased in understanding economic and income segregation. Much of the new concern with understanding economic segregation has revolved around the arguments that segregation, especially of the poor, leads to negative outcomes in quality of life and poorer access to high quality resources, such as good schools. This growing interest in social and economic inequality is also providing an impetus for studies of segregation. These issues continue to drive the interest in, and research on patterns and causes of residential segregation.

Resilience

Christoph Steinebach, School of Applied Psychology, Zürich University of Applied Sciences, Zürich, Switzerland

Abstract

The capacity of people to withstand obstacles in their lives consistently impresses. What distinguishes those who demonstrate 'resilience?' And, how can we promote this capacity in education and therapy? The first section of this article gives an overview of the complexity of relevant questions. There are overlaps with the theory, research, and practice of positive psychology, as well as the concepts of optimal development and health. These are discussed in the second section, where explanations of resilience are given from different perspectives and research approaches. These largely theoretical considerations refer to the basics of theory and practice of promoting resilience. Subsequently, diagnosis, prevention and intervention, and evaluation are described. The final section provides a view on future developments.

Many myths, heroic legends, and biblical stories tell of people who faced special challenges, who mastered the most significant stresses with their own power, and who emerged stronger from crises. Given this historical interest in the theme, it is all the more surprising that research in the behavioral and social sciences has only relatively recently taken up the theme of 'resilience.' Today, theories and models of resilience are discussed with respect to situations when there is a need to regain balance in the face of stress or crisis. Resilience, in fact, has two related components: (1) the act of trying to handle stress or difficulties and (2) the gain in stress management skills and personal development that may occur through this process of learning to cope with difficulties. This concept relates not only to individuals but also to groups, organizations, communities, and societies (Fletcher and Sarkar, 2013). It relates more generally to all creatures, plants, and landscapes (e.g., under the stresses of climate change) (Béné et al., 2012; McElwee, 2007), as well as to objects and materials under severe conditions.

Development of a Program

As convincing as personal or anecdotal experiences may be, 'resilience' is difficult to define scientifically. Lacking a clear description of the term, one happily turns to metaphors and references the football or the comb made of horn which regain their shape and "… who will 'bounce back' from earlier dysfunction" (Luthar, 2006: 745). Indeed, research has shown that people respond very differently to severe stress (Rutter, 2013; Werner and Smith, 2001), with some carrying on in the face of adversity, while others suffering severe disruption to their lives. The first step toward developing a deeper understanding of resilience has been to describe the resiliency of individuals, beginning with the study of resilience in young people. The focus of this research was first on individual characteristics, then on external factors, and finally on the process of dealing and coping with critical life events and circumstances (Davis et al., 2009). The questions of how individual and environmental factors directly influence the way in which a person copes with stressful events and living conditions, as well as the more complex and indirect processes by which individual competencies and strengths influence the systemic interactions between the individual and his or her environment have become increasingly important (McElwee, 2007; Ungar et al., 2013; Fletcher and Sarkar, 2013).

Questions and Observations

Issues related to resilience are diverse. Research and practice on 'resilience' must, therefore, meet a range of requirements. Kaplan (2005) argues that it is necessary to discuss whether the concept and research results have any specific meaning, and if they will endure over time. From this point of view, he critiques the breadth of the approach and the weaknesses of the measurements.

Factors: What are the risk factors and protective factors that influence the vulnerability of a person or a social system? In her early work, Emmy Werner pointed out the importance of social support for positive development despite exposure to stress (Werner and Smith, 1982; Rutter, 2006). Being part of a family might provide help and integration (e.g., social support, McElwee, 2007) and emotional support (e.g., social bonds, McElwee, 2007). Conversely, legal separation and divorce are risk factors that can be connected to particular pressures. The ways in which these protective and risk factors influence outcomes depends on the context in which they are present. For example, for children it is crucial whether the separation of the parents was preceded by long-term serious conflicts (Rutter, 2013). In addition, Rutter further shows that there are substantial interactions between genetics and environment.

Genes and environment: As current behavioral genetics shows there are diverse and fundamental interactions between the genetic makeup of a person (genes, G) and the risk factors in the environment (environment, E) of that individual. "G × E relies on studying an environmental risk factor for which there is good evidence of substantial risk, and of environmental mediation of that risk, as well as heterogeneity in outcome" (Rutter, 2006: 4). Such relationships are discussed inter alia for antisocial behavior as a function of monoamine oxidase (MAO) activity and neglect in childhood, the effects of abuse in childhood and vulnerability to depression moderated by the serotonin transporter 5-HTT gene (Rutter, 2006; Feder et al., 2009), and "the valine variant of the COMT gene in relation to the effects of early heavy use cannabis,

schizophrenia being the outcome variable" (Rutter, 2006: 4; catechol-O-methyltransferase COMT, Feder et al., 2009; see the next section). As these results show, genetic effects can be partially demonstrated only under specific environmental conditions. The effects of such G × E interactions are rather specific. Hence, there cannot be a single 'resilience trait' (Rutter, 2006: 6). Rather it has been suggested that G and E "share the same pathophysiological pathway" (Rutter, 2006: 6). Genetic variation is not alone, in and of itself, a risk or protective factor (Rutter, 2006). "Adverse or positive early life experiences lead to 'biological embedding' via gene–environment interplay, and shape brain and body; in the end they bias the individual to react in certain ways to stressors generated both externally and internally" (Karatoreos and McEwen, 2013: 341). In addition to pregnancy, the neonatal period, and the childhood, the adolescent period is considered to be particularly sensitive to 'biological embedding' by affecting the process of allostasis. Allostasis refers to the ways in which people cope with stress on a muscular, neuronal, and biochemical level, on the emotional and cognitive level, and the ways in which they use bodily and behavioral changes to adjust appropriately and to brace themselves for new burdens. Therefore, allostasis consists not only of attaining an internal equilibrium, but it also entails establishing new defaults that represent an improvement in the ability to calm down and cope with stress, allowing for greater stability than previous levels ('stability through change,' Karatoreos and McEwen, 2013: 338).

Psychophysiology and brain: Different hormonal substances, neurotransmitters, and neuropeptides all play an important role in maintaining and regaining allostasis (Wu et al., 2013; Feder et al., 2009): the hypothalamic–pituitary–adrenal (HPA) axis influences susceptibility to anxiety disorders after childhood abuse (Wu et al., 2013; Feder et al., 2009); the noradrenergic and dopaminergic systems influence the risk of serious posttraumatic disorders (Wu et al., 2013); and serotonergic systems in interaction with environmental conditions may increase the individual's vulnerability to stress and depression. In addition, the dopaminergic systems may increase the risk of reduced resilience and stress management. Neuropeptide Y (NPY) is associated with increased susceptibility to anxiety disorders after neglect and abuse in childhood (Wu et al., 2013). In addition, the brain-derived neurotrophic factor (BDNF) has been shown to interact with stress and to promote depression and anxiety (Wu et al., 2013; Feder et al., 2009). Epigenetic mechanisms also determine hardiness to stress (Feder et al., 2009; Wu et al., 2013). The "neural circuitry of fear, reward, and emotion" (Feder et al., 2009: 7–10; Wu et al., 2013) makes a decisive contribution to the development of functional stability of the biophysical system. All these findings "underscore the view that resilience is not simply the absence of maladaptive changes that occur in vulnerable individuals; rather it is mediated by a unique set of adaptive changes" (Feder et al., 2009: 6). The "adult as well as [the] developing brain has considerable structural and functional plasticity and capacity for resilience" (Karatoreos and McEwen, 2013: 340).

Environment: The assumption that risk and protective factors are of equal importance worldwide is certainly wrong. As Rutter (2013) shows, with respect to marriage and divorce, the "main clinical implication [is] the requirement to assess individual needs in relation with particular circumstances, rather than assume that all risk and protective factors have similar effects in all conditions in all people" (Rutter, 2013: 476). Meanwhile, a variety of environmental characteristics that promote resilience have been identified. But what distinguishes an environment that supports resilience from one that does not? Certain elements are of special importance and many are context dependent. For example, in the case of an earthquake, social support and integration, cooperation and networking of services, structure and leadership of the community, and the commitment to the community are of particular importance (Norris et al., 2008). Crucially, the resources themselves must be resilient. They must be robustly designed (robustness), established, and managed, so that they do not collapse when problems arise. The strategies and resources must be 'redundant,' that is they must be available, and, if they become unavailable, backup substitute resources should keep the process of adaptation in motion. Additionally, the system must be built to be able to identify problems and activate more resources when it is threatened (resourcefulness). At a more individual level, the goals that one is striving for must be attainable within a reasonable time frame (rapidity) (Norris et al., 2008: 134, with reference to Bruneau et al., 2003).

Crises: Which challenges and stressors, crises or traumas are considered so serious that they require resilience? "Problems in life are inevitable. From daily hassles to major traumatic events, considerable research effort has focused on the potential short- and long term negative consequences for mental and physical health" (Davis et al., 2009: 1637). Type, quality, and timing of stress may be crucial. These receive their real meaning only when they are measured relative to the coping resources of the individuals in their environments. What is a great burden for one person may hardly pose a challenge to another, because they have enough personal resources or can rely on the support in their environment (Steinebach, 2012). Often, smaller everyday challenges offer the chance to steel oneself for times of trouble (Rutter, 2013).

Lifemanagement: What are the critical signs for coping and growth? "[G]ood coping, opportunities for growth, beating the odds, and inoculation against future stress" (McElwee, 2007: 59) are related to resilience. Aggression, withdrawal, and excessive control are seen as 'unhealthy resilience' (McElwee, 2007: 59). Even when 'healthy' and unhealthy ('catastrophe') reactions are well differentiated, the full process of coping must be observed. It may be that after a period of hapless attempts to cope, the goal is finally achieved. This process of learning and struggling through difficulties can result in an increase in overall personal resources and further positive development. The assessment of whether resilience is present requires an evaluation of the coping process over time (Steinebach, 2012; e.g., for the detection of a 'steeling' effect, Rutter, 2006: 2).

Concepts and Definitions

The roots of the word 'resilience' are the Latin words 'salire,' to jump, and 're,' back (Smith et al., 2013: 167). Correspondingly, 'resilience' at its root means that an initial state is regained: subjects regain their earlier form, the equilibrium in systems or rebalances in humans, and stress and trauma are replaced by feelings of well-being. Increasingly, however, several other

aspects of resilience are discussed: (1) Resilience is reflected in the interplay of the complex structure of interrelated environmental factors (e.g., Ungar et al., 2013) whose significance at first glance might be seen as quite neutral or even 'risky' (Rutter, 2013: 477). (2) Resilience is understood not only as a possible response to crises, but also as a positive response to the challenges of everyday life (Masten, 2001; 'chronic adversity versus resilience following single-incident traumas,' Bonanno and Diminich, 2013: 378; 'inoculation and coping,' Rutter, 2013: 477). (3) Resilience suggests positive development beyond mere readjustment (e.g., Davis et al., 2009). Accordingly, there "are several existing definitions of resilience that share a number of features all relating to human strengths, some type of disruption and growth, adaptive coping, and positive outcomes following exposure to adversity" (Prince-Embury, 2013: 9). (4) Resilience is also considered as a dynamic feature of groups, organizations, and larger communities (e.g., Zautra, 2009). (5) Resilience can be observed over the whole life span (e.g., Ong et al., 2009). (6) Finally, it is noted that in all these processes of individuals dealing with stress, cultural differences are taken into account (e.g., Zautra, 2009), as well as the biophysical processes on the part of the individual (e.g., Rutter, 2013; Wu et al., 2013).

'Resilience' is, therefore, seen overall as the positive adaptation and sustainable development of a system to respond to short- or long-term everyday challenges or severe stress. Based on internal system processes and through dealing with the environment, the system defines new reference values and develops required competencies, and the ability to cope with future stresses improves (Ong et al., 2009; Bonanno and Diminich, 2013; 'transformative capacity,' Béné et al., 2012: 21; 'new normal' and 'adaptive trajectory' vs 'growth,' Norris et al., 2008: 132; 'ecological resilience,' Norris et al., 2008: 130).

Boundaries and Interfaces

The following three subsections briefly outline the conceptual relationships of 'resilience' to 'positive psychology' and to theories and models of 'optimal development' and 'health.' Additionally, differences between these concepts also become apparent.

Positive Psychology

A particular concern of positive psychology is overcoming the negative perspective in psychological research, theory, and practice. Similar proposals were initially formulated in the early 1950s. Positive psychology and resilience therefore have common roots (see McElwee, 2007). Since the beginning of this millennium, 'positive psychology' is understood as 'the scientific study of what goes right in life' (Peterson, 2009: 3). Thus, topics of interest include character strengths, happiness, courage, mindfulness, humor, confidence, and optimism. In addition to such individual character attributes, strengths of families, groups and teams, organizations, communities, and societies are examined (Brendtro and Steinebach, 2012; Steinebach, 2012). The strengths addressed in the theories and models of resilience are seen as protective factors that are features of the person or their environment (e.g., Smith et al., 2013). On the other hand, these strengths are considered criteria for successful adaptation and coping with stress, crises, and traumas. Accordingly "the study of resilience … [has] overturned many negative assumptions in deficit-focused models" (Goldstein and Brooks, 2013: 6). However, following Luthar (2006), we must point out several significant differences between positive psychology and 'resilience': (1) In addition to the positive factors of behavior and experience, resilience takes into account difficulties and risk factors. Resilience is evident only in dealing with stress. (2) The sustainable development of resistance is revealed only over the course of an individual's development. For this reason, development over the whole life span must be observed. (3) Resilience is developed, implemented, and promoted in a complex interchange of environmental, cognitive-emotional, and biophysiological processes. The biological basis of this process has, to date, been insufficiently accounted for in positive psychology. (4) Positive psychology does not examine negative aspects of development; however, the concept of resilience does address these aspects (Ungar and Lerner, 2008). Increasingly, it becomes clear that while wishing to emphasize strengths, as demanded by positive psychology, negative aspects of individual characteristics and the environment must also be taken into account. When integrating strengths into such an approach, as promoted by positive psychology, negative aspects of the individual and their environment must also be considered to reflect the complexity of human experience and behavior. This is particularly true because after an event, whether a personality trait or an environmental factor was positive or negative and whether the resilient coping with stress will endure are only revealed over time. Finally, we cannot assume that gains in resilience will be lifelong (Rutter, 2006).

Optimal Development

In struggling with tasks, challenges, stresses, and crises, the strengths and weaknesses of individuals and their environments become clear. This raises the question of how individuals can become competent to manage their development independently and 'optimally,' given all the challenges. Starting from the cybernetic theory of adaptive self-optimizing systems (Steinebach, 2000), flexible goal attainment by individuals and improvement of their own resources prove to be an important guarantee for optimal development. These elements are also an expression of sustainable resilience, which not only restores the original state, but also promotes successful further development. An adaptive self-optimizing system has several elements, which in their interplay are also able to define new reference values. Corresponding ideas and processes are considered in different models: for example, the model of selection, optimization, and compensation (Baltes and Baltes, 1990); the two-process model of assimilation and accommodation (Brandtstädter, 2009); or in the life course theory of control (collectively, Lang and Scheel, 2012). "We may ask ourselves how we can sustain a good life under adversity, what aims in life we should fight hardest to preserve, which voice within do we listen most, and how do we set our priorities for the future in the face of limited resources" (Zautra, 2009: 1938). We assume that comparable processes also occur on biochemical, neural–muscular, emotional, and cognitive levels and

contribute in terms of semiautonomous system processes to a successful interplay between person and the environment; for example, in dealing with chronic stress to maintain allostasis (see Section Questions and Observations). In order to appropriately map the various environmental aspects, the systematization of Bronfenbrenner (1989) is particularly useful. He distinguishes between the micro-, meso-, exo-, and macro- and the chrono-systems. He describes ecological transitions as the central driving force for development and calls for research, which has ecological validity and that takes into account this diversity of systems. As the work of Ungar shows (Ungar et al., 2013), this model allows for a multi-systemic understanding of resilience, which reflects the heterogeneity of the environment of the individual. Furthermore, the cybernetic theory of adaptive self-optimizing systems points out the importance of having competencies in the accurate perception of external and internal processes, the importance of differentiated self- and environmental models, and a sensitive perception of an individual's own needs and motives. This theory also points out the importance of effective executive functions (Hughes, 2011).

Health

Health is affected not only by biological factors but also by emotional and cognitive processes. Several elements are crucial for facilitating positive health behaviors, including attitudes and a supportive environment (e.g., the family and the workplace), which includes culture and society at large. Therefore, both health and resilience are seen as proof of a successful interplay of personal and environmental conditions (Ungar and Lerner, 2008). The Ottawa Charter of 1986 strongly shaped the current model of health promotion. In focusing on health instead of disease and the contribution of the individual and the society for the preservation and promotion of health it rejects the biomedical model. If health is more than the absence of diseases, the focus falls on general well-being (World Health Organization, 1986, 2009). As Antonovsky (1996) asked which factors make health and well-being possible, despite both everyday and occasional extreme stress. Accordingly, the Ottawa Charter defined health promotion for individuals as the "… process to increase control over, and to improve, their health" (World Health Organization, 2009: 1). In this perspective, health promotion, according to the Bangkok Charter, provides "… a positive and inclusive concept of health as a determinant of the quality of life and encompassing mental and spiritual well-being" (World Health Organization, 2009: 24). Well-being as a central component of health does not mean that environmental aspects are overlooked. Health promotion targets both humans and environments. The environment is understood as a system of various components, from the interpersonal level to politics, society, and culture. Communities as life-spaces are seen as especially relevant.

Motivation is seen as crucial factor for healthy behavior. When are people motivated to take an active role in the direction of their lives and to take care of their own health? Following Ryan and Deci (2000), we can assume that three needs are guiding individuals: competence, autonomy, and relatedness. If an action serves these needs, people become active, committed, and feel comfortable. The experience of belonging (e.g., to a group) is an essential component of identity. The autonomy from requirements of others allows people to react according to their own interests, expertise, and experience which ensures self-confidence.

Successful self-control has a positive effect on well-being (Bandura, 1998; Sternberg and Spear-Swerling, 1998). This is also reflected at the level of psycho-physiological processes. To the extent to which positive affect is associated with health, those positive feelings are considered as protective factors (Steptoe et al., 2009). Thus, we can find biological correlates of positive affect that are of great importance for health and life satisfaction.

Principles and Practice of Promoting Resilience

The definitions of 'resilience' highlight the important elements of the concept: confrontation with adversity and successful management of both the self and/or the environment. Decisions about proper diagnosis, the appropriate practice of preventive services, and intervention and evaluation design are strongly influenced by the underlying theory defining the preferred model.

Assessment

Assessment in resilience promotion requires the differentiated monitoring and evaluation of the strengths of individuals, their environments, and the existing interactions between person and environment. The question of objective, reliable, and valid assessment of resources ('assessment challenge,' Prince-Embury, 2013: 13) is crucial. The focus on resource assessment aims to supplement the deficit-related diagnosis and helps to identify target groups for prevention and intervention. However, for many problems there are no models with high explanatory value and reliable assessment methods (Goldstein and Brooks, 2013). Differentiated profiles of strengths and risks from individuals to culture would facilitate designing interventions (Rutter, 2013). Finally, only repeated assessment enables the reliable monitoring of gradients of improvements and effects of interventions. To evaluate interactions between individuals and their environment as elements of the assessment process, personal traits and features of the environment as well as the competency of individuals in shaping their own interactions with the environment are assessed (Petermann and Lohbeck, 2013). In the multimodal resources assessment questionnaire, interviews, checklists, and behavioral observations are used. Individualized diagnosis may be necessary, which has, to a large extent, a situation-specific implementation and which might be supplemented by physiological parameters (Zautra, 2009; possibly supplemented by 'ecological momentary assessment,' Steptoe et al., 2009: 1748).

Prevention and Intervention

Assessment is a good starting point for prevention and intervention, especially when also trying to evaluate causal relationships. The assessment process also takes into account those conditions that are important for the implementation of the intervention (Rutter, 2013). What distinguishes effective

interventions? Luthar (2006) identifies the following features of effective interventions: (1) interventions are likely to be effective if they are aimed at a target group with a high-risk potential; (2) they should be aimed at aspects of behavior and experiences that are relatively easy to change; (3) interventions should be geographically close to the targeted people, easily accessible, and reliable; (4) interventions should not be too short-term, rather they should last longer in order to support people in everyday life; (5) interventions should support the development of new resources and competencies, and the activation of available strengths. In addition, the conceptual broadness of 'resilience' seems to recommend an approach that (6) takes into account both the strengths and weaknesses of the individuals and their environments. Such offers are aimed at (7) changes at several levels (e.g., physical, emotional, and cognitive) and in several environmental areas (e.g., family, school, and workplace, for instance, Ungar et al., 2013; 'Multidimensional Treatment Foster Care,' Leve et al., 2009: 1869) in order to ensure sustainability. In addition to this interventions should be offered early. They both reduce risk factors, and expand and stabilize strengths. For example, to help build the 'Five Cs' (competence, confidence, connection, character, and caring for; Lerner et al., 2005: 12), which are the core concepts of positive youth psychology. "… [S]uch programs are most likely to result in the development of these Cs when they involve sustained positive adult–youth relationships, youth skill-building activities, and opportunities for youth participation in and leadership of community-based activities" (Lerner et al., 2005: 12).

Evaluation

The evaluation of measures to promote resilience is not easy. Rigorous evaluation requires differentiated, mostly quasi-experimental designs, with large sample sizes. The factors and processes to be considered are highly complex and dynamic (Ungar et al., 2013). If interventions are to be ethically and professionally appropriate, an evidence-based practice is essential. Evaluation is not only useful for research and theory development, but it also serves to help in the optimization of practice. Promotion of resilience in this sense is understood as evidence-based practice. The evaluation of practice then provides important insights for the improvement of theory and how to transfer this same theory into practice (e.g., Leve et al., 2009). Due to the complex nature of the interventions, evaluation is an interdisciplinary concern. With the variety of results from disciplines such as medicine, psychology, educational science, and sociology, the task is to continually integrate the most important evaluation and research results. To date, we summarize, based on the work of Rutter (2006), the main findings of resilience research: (1) resilience can develop in dealing with challenging environmental conditions – even more than when risks are avoided; (2) protective factors can prove to be neutral or risky in the absence of threat or stress; (3) protection can also arise from what people do to deal with stressful situations; (4) protection may arise from conditions that emerge long after the exposure to stress. Therefore, longitudinal multifocal and multi-methodological evaluations are required. Short-, medium-, and long-term effects should be considered in different situations and life stages (e.g., Leve et al., 2009).

Outlook

We defined 'resilience' as the positive adjustment and sustainable development of a system to cope with short-term or longer lasting everyday challenges or severe stress. Resilience is understood as the result of internal system processes in dealing with the environments of the system. Resilience can lead to adaptation or to the development of new reference values and skills to facilitate stress management, which helps to face upcoming loads. Thus, resilience is understood as a systemic process of development, and as an expression of a highly complex systemic action. In this complex subject, those interventions that are effective act at different levels at the same time, consider different methods to address the person in terms of a holistic empowerment and promote positive environmental aspects.

In the future (1) it will be important to develop more interdisciplinary, participatory, and sustainable models of practice. In these models, the focus is on the development of skills of self-control (e.g., 'awareness' and 'mindfulness,' Methods of Cognitive–Behavioral Therapy) as well as on environmental measures (promotion of cohesion in the community, commitment, and transparency in planning processes).

Applied research faces the challenge of appropriately evaluating the different interventions to ensure the comparability of research processes and methods despite the diversity of practice. (2) Substantial insights can be gained if – in addition to large-scale evaluations – the scientific evaluation of smaller projects becomes a matter of course. In addition, it will be important to connect processes and changes on neurophysiological, emotional, and cognitive levels with changes in environmental systems.

Resilience is about learning and development in everyday life. In interaction with the environment, skills and resources are developed. The person is an active actor, as is the environment. The environment provides resources that offer the individual support and assistance. The ability to secure resources in the appropriate environment is an important competence. In addition, all people have a duty to support the resilience of others. (3) We are asked to provide resources and develop our own as competencies for our own and for the sake of others. Cultures may vary in their modes of nurturing resilience. The promotion of resources to cope in everyday life with all its hardships and crises is certainly a strength with benefits for everyone in every culture and society.

Resilient City

Danny MacKinnon, Newcastle University, Newcastle Upon Tyne, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides a review of the idea of the resilient city, which has become influential in recent years. The concepts of resilience and urban resilience are defined in the introductory section. The article then proceeds to outline the influential ecological conception of resilience and its application to cities, before highlighting some recent criticisms of this approach. The remainder of the article discusses developments in three main areas of research: adaptation to climate change and natural disasters, urban governance and institutions, and urban economic resilience. Finally, a brief summary highlights the main points of the article.

Introduction

The concept of resilience has attracted growing interest in urban and regional studies and public policy in recent years. It can be defined as the ability of an entity or system to recover its form and function following a disturbance or disruption of some kind (Simmie and Martin, 2010: 28). As such, the resilient city refers to its capacity to deal with external sources of stress and maintain or recover normal functioning in terms of dimensions such as economic production, transportation, housing, energy transmission, and social interaction. Key sources of disturbance include natural disasters such as Hurricanes Katrina or Sandy, climate change, international terrorism, and economic downturns such as that resulting from the financial crash of 2007–08. Such events focus considerable attention on the responsive capacities of cities to anticipate, manage, and adapt to change (Dawley et al., 2010). There are close parallels between resilience and the concept of sustainability, particularly in terms of the underlying imperative for cities and communities to become more resilient in the face of a range of externally derived environmental, economic, or political threats, which seems uncontentious and commonsensical (Swyngedouw, 2007). Indeed, Foster (2010: 3) claims that resilience is to the 2000s and 2010s what sustainability was to the 1980s and 1990s.

Resilience is becoming 'a pervasive idiom' of urban governance (Walker and Cooper, 2011: 144), requiring strategies for disaster mitigation and the protection of critical infrastructures as well as the development of procedures to anticipate and preempt key threats. The context for such strategies is derived from natural disasters such as Hurricane Katrina, which devastated much of New Orleans in 2005, and terrorist incidents like the attacks on New York in 2001 and Mumbai in 2008. Levels of resilience reflect a city's vulnerability to surprise and shock in the sense that high vulnerability is associated with low resilience, implying a strong degree of exposure to potential threats and a lack of anticipation and preparedness (Foster, 2010: 4–5). The term is also invoked by progressive social and environmental movements that are aiming to cultivate alternative social relations based upon environmental sustainability and social well-being rather than economic growth. From this perspective, resilience has connotations of ecological and social stability and integrity that are consistent with initiatives to localize the supply of food and energy, contrary to the environmentally destructive practices of global capitalism (Hudson, 2010). As such, the resilient city is not only a popular concept, but also a contested one that is capable of being deployed and mobilized by different groups in different ways.

Resilience and Cities

The concept of resilience has roots in both physics and mathematics, where it refers to the capacity of a system or material to recover its shape following a displacement or disturbance (Norris et al., 2008), and ecology where it emphasizes the capacity of an ecosystem to absorb shocks and maintain functioning (Holling, 1973). Subsequent applications to a number of objects from the built environment to individuals, social systems, and communities have spawned a range of definitions (Table 1). The work of the American ecologist C.S. Holling (1973, 2001) has proved particularly influential, not least through his role in groups such as the Resilience Alliance of scientists and the Stockholm Resilience Centre, a high-profile think tank. In the ecological literature, two types of resilience are commonly identified. The first is 'engineering resilience,' which is concerned with the stability of a system near an equilibrium or steady state, where resilience is defined in terms of elasticity, which emphasizes resistance to disruption and speed of return to the preexisting equilibrium. Second, 'ecological resilience' refers to external disturbances and shocks that result in a system becoming transformed through the emergence of new structures and behaviors. As these concepts suggest, resilience is based upon systems thinking and particularly the notion of complex adaptive systems based on nonlinear dynamics and self-organization, meaning that large-scale structures tend to emerge spontaneously from the interactions between microlevel processes (Holling, 2001).

Resilience is closely associated with the ecological idea of 'panarchy,' which emphasizes the evolutionary character of adaptive cycles seen as nested within each other across time and space (Holling, 2001). Four key phases of the evolution of an ecosystem such as a forest are identified, each of which corresponds with a particular level of resilience (Figure 1). The first 'exploitation' phase, which equates to the early phase of development, is defined by rapid growth and high

Table 1 Selected definitions of resilience

Author, date	*Discipline*	*Level of analysis*	*Definition*
Gordon, 1978	Physics	Physical system	The ability to store energy and deflect elasticity under a load without breaking or being deformed
Holling, 1973	Ecology	Ecological system	The persistence of relationships within a system; the ability of systems to absorb change and still persist
Walker et al., 2004	Ecology	Ecological system	The capacity of a system to absorb disturbance and reorganize while undergoing change so as to retain the same function, structure, and feedbacks
Egeland et al., 1993	Psychology	Individual	The capacity for successful adaptation and functioning despite high risk, stress, or trauma
Agder, 2000	Geography	Social	The ability of communities to withstand external shocks to their social infrastructure
Katz, 2004	Geography	Social	Ways in which people adapt to changing circumstances to get by and 'make do' through the exercising of autonomous initiative
Hill et al., 2008	Interdisciplinary social science	Region	The ability of a region to recover successfully form shocks to its economy
Martin, 2012	Geography	Region	Region's resistance to, and recovery from, major economic shocks

Reproduced from: MacKinnon, D., Derickson, K.D., 2013. From resilience to resourcefulness: a critique of resilience policy and activism. Progress in Human Geography 37, 253–270. http://dx.doi.org/10.1177/0309132512454775. http://phg.sagepub.com/content/early/2012/08/08/0309132512454775; Adapted and extended from: Norris, F.H., Stevens, S.P., Pfefferbaum, B., Wyche, K.F., Pfefferbaum, R.L., 2008. Community resilience as a metaphor, theory, set of capacities, and strategy for disaster readiness. American Journal of Community Psychology 41, 129.

resilience as resources are accumulated and openness and emergence promote adaptability. A successful forest moves into the 'conservation' phase as it matures, resulting in reduced resilience as internal relationships become fixed and rigid. This renders the ecosystem vulnerable to external shock and stress, which propels the transition to a third 'release' phase based on crisis and destruction, involving the expulsion and exhaustion of accumulated resources (Holling, 2001). This facilities a fourth phase of 'reorganization' through experimentation and renewal as new arrangements begin to emerge and take hold. Resilience is initially low in the release phase, but begins to increase as the remnants of the system become sensitive to external forces and reorganization gathers momentum. The underlying idea is that ecosystems maintain their resilience by undergoing such cycles, with destruction essentially purging the system of its vulnerability and paving the way for renewed growth (Swanstrom, 2008).

In recent years, the ecologically rooted concept of resilience has rapidly infiltrated the fields of urban governance and planning, based on concerns about security, critical infrastructure management, public health, economic development, and planning. Walker and Cooper (2011: 2) argue that the success of resilience in 'colonizing multiple arenas of governance' reflects its ideological fit with neoliberalism as the dominant contemporary approach to economic policy that espouses individual self-reliance, competition, and private property rights. In an urban context, neoliberalism is associated with a framework of spatial competition in which cities compete for investment, markets, and resources. Enhanced urban competitiveness is seen as the underlying source of economic success and prosperity, based upon the

Figure 1 Ecological studies of resilience propose a four-phase cycle of system adaptation and change. Adapted from: Holling, C.S., Gunderson, L.H., 2002. Resilience and adaptive cycles. In: Gunderson, L.H., Holling, C.S. (Eds.), Panarchy: Understanding Transformations in Human and Natural Systems. Island Press, Washington DC, pp. 63–102.; Pendall, R. et al., 2010. Cambridge Journal of Regions, Economy and Society 3, 71–84.

harnessing of local resources and assets through initiatives that seek to upgrade workforce skills, stimulate the formation of new firms, and develop new facilities and cultural attractions (e.g., shopping centers, conference venues, hotels, and museums). Resilience thinking derived from ecology serves to reinforce and extend the focus on cities and regions as units of competition, emphasizing the need for flexibility and responsiveness in the face of a range of external threats.

Resilience can be seen as the latest in a long line of naturalistic metaphors to be applied to cities (Gandy, 2002). Organic conceptions of cities as systems displaying natural traits such as growth, competition, and self-organization have proved particularly influential, informing the urban ecologies of Patrick Geddes, Ebenezer Howard, and the Chicago School (Evans, 2011). The use of natural metaphors had implications for the governance and management of cities into the twentieth century, as Gandy (2002: 8) observes:

> In the twentieth century, a range of technological advances facilitated a new mediation between organic metaphors and the production of urban space. In 1965, for example, the engineer Abel Wolman outlined "the complete metabolism of the modern city" as the culmination of advances in the technical organisation of urban space. Yet these metabolic metaphors treat the city as a discrete physical entity. The "body of the city" is considered in isolation from wider determinants of urban form, and the social production of space is downplayed in relation to the technical mastery of cities.

In the context of scientific efforts to create more resilient urban infrastructures, Evans (2011: 224) suggests that ecology may come to play a key role in the shaping of twenty-first century cities. Informed by theories of ecosystems as complex adaptive systems, this new urban ecology conceives of the city as a social–ecological system, in which biophysical and social factors are linked by multiple feedback loops and exhibit the common properties of resilience and complexity (Evans, 2011: 229). The effect is to naturalize cities as self-contained systems by divorcing them 'from wider determinants of urban form' such as flows of capital and modes of state regulation (Gandy, 2002: 8).

In their critique of the notion of resilient cities and regions, MacKinnon and Derickson (2013) argue that the ecological concept is conservative when applied to the social sphere, referring to the stability of a system against interference. This is invariably defined in terms of recovery, rebound, and return to a preexisting set of norms, notwithstanding notions of 'bounce forward,' which commonly project these existing norms into the future. The implication of the extension of ecological thinking to the social sphere is that human society should mimic the decentralized and resilient processes of nature (Swanstrom, 2008: 15). Deference to 'the emergent order of nature' (Swanstrom, 2008: 16) is implicitly extended to society as existing social networks and institutions are taken for granted as 'natural' and harmonious. As a result, the existence of social divisions and inequalities tends to be glossed over. Ecological models of resilience are fundamentally antipolitical, viewing adaptation to change in terms of decentralized actors, systems, and relationships and failing to accommodate the critical role of the state and politics (Evans, 2011). This prompts Swanstrom (2008: 16) to argue that the ecological model of resilience is 'profoundly conservative' when it is exported into a social context. This conservatism is reinforced by the normative aspect of resilience, which is assumed to be always a positive quality, imbued with notions of individual self-reliance and triumph over adversity.

Urban Resilience, Climate Change, and Disaster Management

Research on urban ecological resilience tends to operationalize the term 'resilience' as it pertains to the ability of cities to both withstand sudden dramatic shocks such as a major weather event and adapt to more long-term disruptions such as those related to climate change, which refers to a long-term shift in underlying weather patterns that results from a range of natural and human-induced factors. The Community and Regional Resilience Initiative in the Southeast of the United States, for instance, defines resilience as "a community's capability to prepare for, respond to and recover from significant multi-hazards threats with minimum damage to public safety and health, the economy and national security" (Colten et al., 2008: 20). Enhancing a community's resilience involves a fourfold process of anticipating major multihazard threats, reducing its overall vulnerability to hazard events, responding to such events when they occur, and longer term recovery from them (Colten et al., 2008). This framework is then used to assess the resilience of New Orleans in the face of Hurricane Katrina. The likelihood of such an event had been widely anticipated following experience of previous hurricane strikes and the accurate tracking of Katrina across the Gulf of Mexico, but planning did not anticipate the widespread and massive levee failure that occurred, resulting in the inundation of about 80% of the city. As has been widely documented, the response was slow and inadequate. Subsequent recovery has proved highly uneven with the economy recovering fairly well, while repopulation and rehousing has been slower, particularly in the most severely affected areas of Eastern New Orleans, which are predominantly African-American. Reduction of the city's vulnerability to future events has focused on the hurricane protection systems of levees and pumps and a revamping of emergency response planning, although progress has been slow and the fundamental sources of geophysical and social vulnerability in New Orleans – its below sea level position; accelerating subsidence; rising sea levels; exposure to storm surges and hurricanes, together with development in low-lying areas; poverty; aging segments of the population; and large groups that lack access to private transport – remain in place.

Climate change poses a variety of challenges to cities across the world, especially those in coastal locations, prompting city leaders and governments to assess a range of vulnerabilities, impacts, and adaptation options (Leichenko and Thomas, 2012). In this context, resilience spans the ability to resist or withstand impacts and the capacity to recover and reorganize so as to restore previous levels of functioning (Brown et al., 2012: 534). A number of studies have shown how socio-economic conditions interact with physical factors to shape levels of vulnerability and resilience (Leichenko and Thomas, 2012). One stand of research on the vulnerability of coastal regions of the United States, for example, emphasizes that

high levels of poverty, low levels of education, and low median house prices accentuate urban communities' exposure to shocks and undermine their capacity to respond, thus reducing overall resilience (Leichenko and Thomas, 2012). The importance of such socioeconomic factors means that cities in the developing world are often particularly vulnerable to the impacts of climate change (Brown et al., 2012). For instance, cities in Latin America are "not only growing sources of greenhouse gases, but … are also hotspots of vulnerability to floods, heat waves, and other hazards that climate change is expected to aggravate" (Hardoy and Romero Lankao, 2011: 158). Urban growth and fragmentation are key drivers of increased emissions in the region, particularly in terms of transportation, which highlights the contradiction between responsibility for contributing to the causes of climate change and exposure to its impacts. In Mexico City, for instance, private cars, used predominantly by higher income groups, contribute only 18% of daily trip segments but 40.8% of CO_2 equivalent emissions, while public transport accounts for 82% of daily trip segments but 29.5% of CO_2 emissions (Hardoy and Romero Lankao, 2011: 159).

In an effort to enhance the adaptive capacities of urban populations and governments, the Rockefeller Foundation has supported the Asian Cities Climate Change Resilience Network (ACCCRN) since late 2007. ACCCRN is focused on so-called second-tier cities in which more than 60% of the projected increase in population between 2012 and 2050 is expected to occur, initially selecting 10 cities across four countries (India, Indonesia, Thailand, and Vietnam). It has identified 10 key action areas for cities to address in order to increase their resilience to climate change (Brown et al., 2012):

- Climate sensitive land use and urban planning
- Institutional coordination mechanisms and capacity support
- Drainage, flood, and solid waste management
- Water demand and conservation systems
- Emergency management and early warning systems
- Responsive health systems
- Resilient housing and transport systems
- Strengthening ecosystem services
- Diversification and protection of climate-affected livelihoods
- Education and capacity building of citizens

These key themes were identified through an inclusive and iterative process of analysis, planning, and engagement that involved multiple stakeholders, resulting in a locally owned strategy for each city. This is seen as a model for other cities to adopt, with successful implementation also requiring expanded national and international policy support and financing, alongside increased public awareness and the establishment of new national and local institutions responsible for urban climate change resilience.

Several crosscutting issues emerge from the studies of urban climate change resilience reviewed in this section. First, the political economy of urban development based upon capitalist land markets means that public policies related to climate change adaption are shaped and mediated by myriad private interests (Brown et al., 2012). As such, long-term goals of security and sustainability are often crowded out by short-term commercial and fiscal considerations. Second, questions of equity and social and spatial justice are paramount as low-income groups in cities tend to be most exposed to the impacts of climate change, but least responsible for generating emissions. This requires the adoption of pro-poor strategies based on the improvement of housing conditions, infrastructure, and services. Third, governance and the development of institutional capacity and coordination remain a key challenge since most city governments in the developing world lack the power and authority to develop and implement effective climate change adaptation strategies (Brown et al., 2012). Addressing these deficits requires support from higher levels of government and international organizations and nongovernmental organizations.

Resilience and Urban Governance

Work in this area examines the effects of different institutional arrangements on resilience and assesses how resilience can inform the development of new governance strategies for adapting to external stresses and shocks (Leichenko, 2011). In this context, urban governance refers to the range of institutions and agencies that are involved in governing a particular city.

Research typically stresses the need to anticipate external events and to respond flexibly and efficiently, based upon polycentric and accountable institutions that operate in a transparent and inclusive manner. For instance, Lebel et al. (2006) identify three key dimensions: public participation and deliberation, which are seen as essential to building trust and shared understanding; polycentric and multilayered institutions that support local knowledge and local monitoring and facilitate interaction and feedback between the different levels; and accountable and just institutions that pursue socially just distributions of benefits and risk among the populations they serve. The emphasis on participation, local accountability, and polycentric institutions not only echoes the approach to 'good governance' adopted by prominent international organizations like the World Bank over the past couple of decades, but also reflects the properties of self-organization and decentralization that characterize the ecological concept of resilience (Holling, 1973). The associated suspicion of central authority in resilience thinking has much in common with neoliberal principles of limited government and the 'enabling state' (Walker and Cooper, 2011). This means that the emphasis on self-organization and polycentric institutions remains curiously divorced from the sociopolitical realities of state authority through which resilience policies have often been formulated and implemented, while the emphasis on participation and inclusion raises broader issues of equity and social justice that resilience thinking is poorly equipped to address (MacKinnon and Derickson, 2013).

Much like sustainability, resilience is externally defined as a crucial imperative by state agencies and expert commentators in spheres such as security, emergency planning, economic development, and urban design (Walker and Cooper, 2011). With regard to security, for instance, the identification of 'new' global risks, coupled with political leaders' claims of 'unique' and 'classified' knowledge of potential threats, justified 'the implementation of a raft of resilience policies

without critical civic consultation' following the events of 11 September 2001 (Coaffee and Rogers, 2008: 115). The development and implementation of policies to combat an unpredictable terrorist threat requires what has been termed a 'multiscale governance fix' (Coaffee and Murakami Wood, 2006: 509). This involves a partial rescaling of security from the national to the urban levels of governance through a range of physical and technological controls at specific sites (e.g., visible policing and security patrols, closed-circuit television), often supported by legislative measures and regulatory guidance. These site-specific controls are often temporarily utilized to reborder cities through the hosting of major cultural, sporting, or political events and conferences. Securitization has become increasingly linked to urban economic development through urban marketing strategies stressing the 'safety' and 'security' of cities as places to conduct business (Coaffee and Murakami Wood, 2006).

The emerging literature on resilience in the context of urban economic development emphasizes the importance of strategic planning and 'place-renewing leadership' as "a form of public–private strategic leadership that empowers institutional or social forms of decision-making to absorb and adjust (proactively and reactively) to path-breaking economic change" (Bailey et al., 2010: 462). The role of urban policy makers is to foster the adaptive capacity to enable the renewal and 'branching out' of economic activity from existing local assets, echoing the processes that seem to have underpinned the development of successful regions such as Cambridge (Dawley et al., 2010; Simmie and Martin, 2010). As such, resilience is serving to reinforce and extend existing trends in urban development policy toward increased responsiveness to external conditions, strategic management, capacity building, and the harnessing of local assets. This helps to account for its adoption by urban and regional policy makers, providing a somewhat more muted successor to the 'creative cities' craze of the mid-2000s (Florida, 2002). Like the creative cities script, resilience is a mobilizing discourse, confronting individuals, communities, and organizations with the imperative of ongoing adaptation to the challenges of an increasingly turbulent environment (Peck, 2010: 221). Yet the 'pseudoscientific discourse' of resilience presents something of a paradox of change, emphasizing the prevalence of turbulence and crisis, but accepting them passively and placing the onus on communities to get on with the business of adapting (Evans, 2011: 234). The effect is to naturalize crisis, obscuring the social roots of 'shocks' such as economic downturns, ongoing processes of climate change and terrorist attacks, as well as the social sources of vulnerability to natural disasters such as hurricane strikes and tsunamis.

Urban governance agencies have placed increasing emphasis on the social and community aspects of resilience in recent years as part of an effort to raise public awareness of potential threats and to encourage increased 'responsibilization' by involving citizens and communities in their own risk management (Coaffee and Rogers, 2008: 113). In the United Kingdom, community resilience has been redefined in terms of 'communities and individuals harnessing local resources and expertise to help themselves in an emergency' (Cabinet Office, 2011: 4) as part of the Coalition Government's 'Big Society' program of renewed localism and voluntary action since 2010 (Featherstone et al., 2012). This fosters an internalist understanding of the local, which sees the sources of resilience as lying within the particular city, neighborhood, or community in question, particularly through the identification of specific assets, capacities, and resources to be cultivated and mobilized. The notion of community resilience has also been adopted by a range of community groups and initiatives such as the rapidly growing Transition Towns movement (Carnegie UK Trust, 2011). While couched within a tradition of radical localism and community action, these 'bottom–up' initiatives echo the language of self-help and self-reliance that animates mainstream policy. The 'Big Society' context in the United Kingdom indicates that arguments for greater urban and community resilience can be utilized to support a program of fiscal austerity involving reductions in public expenditure (Featherstone et al., 2012). In the context of uneven geographical development and entrenched social inequality, there is a sense in which the promotion of decentralized governance and participation as a means of enacting 'resilience' risks simply reinvigorating the trope of individual responsibility with a renewed 'community' twist. Moreover, viewing the sources of resilience as lying within a particular community or neighborhood can all too easily foster a deficit model of policy, which identifies particular areas (often low-income ones) as problematic due to an apparent lack of internal capacity, leadership, or social capital (Mohan and Mohan, 2002).

The Resilience of Urban Economies

A third key strand of research is concerned with the resilience of urban economies (Leichenko and Thomas, 2012). Definitions of urban economic resilience in the literature span three interrelated dimensions: the ability of an urban economy to withstand external pressure (resistance), its capacity to respond positively to external change, and its longer term adaptability or learning capacities (Davies, 2011; Hudson, 2010). Martin (2012) applies this idea of economic resilience by examining the responses of UK cities and regions to the major recessions of 1979–83, 1990–93, and 2008–10. The first recession had the greatest impact on the old industrial regions of the peripheral and northern United Kingdom, whereas the 1990–93 downturn affected the greater South East and Midlands most severely, and the effects of the post-2008 recession have been less clearly differentiated, although Northern and peripheral regions such as Wales, Northern Ireland, Yorkshire–Humberside, and Scotland have been disproportionately affected.

In a preliminary empirical exploration, Simmie and Martin (2010) apply the panarchy model of adaptive cycles (Figure 1) to the UK cities of Cambridge and Swansea. They identify that the former has undergone three main phases since the 1960s of 'reorganization,' 'exploitation,' and 'conservation,' while Swansea has experienced six: 'release' in terms of the decline of traditional extractive industries; the reorganization, exploitation, conservation, and release phases of a model based on the attraction of foreign direct investment (FDI); and recent efforts to establish a new growth path. The Cambridge economy proved far more resilient in response to the early

1980s and 1990s recessions with University-related research providing a strong platform for the growth of a high-tech innovative economy. In Swansea, by contrast, manufacturing employment never fully recovered from the shock of the early 1980s recession and FDI in consumer electronics was unable to provide a sufficient basis for sustained growth. Prosperous cities such as Greater London or Cambridge invariably emerge as more resilient than less favored ones like Swansea or Newcastle from such analyses, reflecting their greater capacities for adaption and diversification over time. These differences in performance are not simply the result of divergent endogenous capacities for innovation, capacity building, and leadership as ecological conceptions of resilience would suggest, but are bound up with the operation of a range of wider political and economic relations that have positioned cities such as London as leading world cities and old industrial cities like Swansea as economically marginal.

Other research has examined the economic restructuring and adaption of industrial city-regions in Europe and beyond since the 1980s (Beatty et al., 2006; Grabher, 1993). Different forms of recovery and reorientation have been identified, particularly in terms of the contrast between industrial cities in France and Germany, which have tended to focus on diversification into new but related technologies and their British equivalents, which largely relied upon the attraction of unrelated industries and services through FDI. The former group has certainly proved more resistant to deindustrialization, although not at the expense of longer term adaptability, while many former industrial cities in the United Kingdom have become highly dependent on public services, leaving them exposed to future cutbacks in expenditure. Research on the renaissance of so-called phoenix cities in Europe, which had a high proportion of manufacturing jobs in the 1970s, has identified the key factors behind their emergent recovery in the 1990s and 2000s. These include institutional leadership and public funding, physical restoration, a focus on employment and skills, neighborhood renewal, social inclusion, and public investment (Power et al., 2008). Recent analyses of the urban and regional effects of the post-2008 recession in Europe indicate that manufacturing-based cities have often been worst hit (Davies, 2011). In the United Kingdom, research has shown that the impact of the initial 2008–09 recession has been the greatest in those local authority areas in which unemployment was already high in March 2008 when the recession began, meaning that Northern city regions with the weakest labor markets have generally been the hardest hit (Dolphin, 2009).

In another study, Swanstrom et al. (2009) examine how metropolitan areas in the United States have responded to the foreclosure crisis in recent years, defining resilience in terms of three main processes: the redeployment of assets or alteration of organizational routines; collaboration within and across public, private, and nonprofit sectors; and the mobilization and capturing of resources from external sources. They focus on resilience and foreclosure prevention in six metropolitan areas: St. Louis, Cleveland, East Bay (California), Riverside, Chicago, and Atlanta. The first two are defined as weak housing market areas, the second two as traditionally stronger market areas, and the last two as mixed. On the basis of these paired comparisons, they found that Cleveland was more resilient than St. Louis, Riverside performed better than the Bay Area, and Chicago was more active than Atlanta (Swanstrom et al., 2009: 46). Interestingly, while 'horizontal' collaboration between public, private, and nonprofit actors within metropolitan areas was important, Swanstrom et al. (2009) argue that the effects of this would remain limited without support from 'vertical' policies emanating from the state and federal scales of government. Only these institutions can provide the necessary level of resources to support local foreclosure prevention and neighborhood recovery activities. Contrary to much resilience thinking, this indicates that external institutions and relationships can play a crucial role in fostering urban resilience in addition to internal factors.

Summary

As this article has emphasized, the idea of the resilient city has proved highly influential in recent years, referring to the ability of a city to respond to external sources of disturbance and maintain its basic functioning. Notions of urban resilience are derived largely from ecology and systems theory, which emphasize the self-organizing properties of complex, adaptive systems in responding to external disturbances and threats. As such, resilience can be seen as the latest in a line of ecological concepts to be applied to cites, viewing them as self-contained and autonomous entities or units analogous to ecosystems (Evans, 2011). Critics have argued that the ecological model has conservative connotations in the social sphere, accepting existing social relations and networks as natural and worthy of preservation, while having little conception of conflictual social relations, politics, and the state (MacKinnon and Derickson, 2013; Swanstrom, 2008). In an urban context, the ecologically rooted notion of resilience stresses the need for decentralized and polycentric institutions to foster adaptive and responsive forms of governance. At the same time, studies of economic resilience focus attention on the endogenous capacities of cities, often overlooking the role of external linkages and networks. Accordingly, the ecologically based notion of the resilient city tends to foster an internalist approach, which sees the sources of resilience as lying within a particular city, community, or neighborhood. This can easily slide into a deficit model that effectively blames particular groups, areas, and individuals as responsible for a lack of resilience, although some research has pointed to the importance of external relations and institutions (Swanstrom et al., 2009). In response, there is a need for scholars and policy makers to adapt a more comprehensive and critical approach to urban resilience that moves beyond the confines of ecology and systems thinking to accommodate the role of wider social, economic, and political relations in shaping the resilience of cities.

This article is a revision of the previous edition article by G. Bridge, volume 19, pp. 13266–13269, © 2001, Elsevier Ltd.

Abstract

This article examines and proposes connections between resource and economic geography from an institutional perspective. Economic geography urgently needs to more substantively embrace resources from its theoretical purview while resource geography's established approaches can be enriched by economic geography's focus on space–place relations, institutional interests and power structures, and the influence of markets on resource use. The article progressively elaborates on the themes of natural resource governance, property rights, evolutionary and spatial dynamics, resource markets, their coordination in value chains and cycles, and the nature of resource peripheries and their remapping that is driven by conflicting institutional considerations.

Contemporary definitions of (natural) resources typically take their cue from Zimmerman's (1933: pp. 3–9) view that "resources are not they become." Thus for Bridge (2000: p. 13266) resources are not 'givens' but "culturally mediated appraisals of the physical environment" that are shaped by economic factors, political institutions, social attributes, and belief systems (see also Mitchell, 1989: p. 1; Hanink, 2000: p. 227). From this perspective, the task of resource geography is truly monumental: to explain how these mediations differentiate and integrate the global economy, and examine their well-being and environmental outcomes. As Geography developed along nomothetic lines after the 1950s, resource or environmental geography became a specialty subject focused largely on concrete problems and policy responses (Bridge, 2000: p. 13266). This applied, ecological emphasis on exploring the relationships between environment, resources, and society remains important. In textbook format, it has been elaborated thematically (e.g., Mather and Chapman, 1995; Mitchell 1989) and with respect to national jurisdictions such as Canada (e.g., Dearden and Mitchell, 2005; Draper, 1998). Research, on the other hand, has emphasized the local expressions in these relationships around the world (O'Riordan, 2001). Moreover, there is growing concern to more fully incorporate resources within economic geography's orbit. This article reflects on these attempts.

While economic geography textbooks invariably recognize the fundamental importance of resources to the global economy, resource exploitation has been peripheral to the subdiscipline's substantive concerns. The rationale for economic geography to address this neglect is urgent and severalfold. First, agglomerations and associated global or local production, value chains, or networks simply cannot exist without resources. Second, the relentlessly powerful centripetal tendencies of economic development simultaneously promote centrifugal tendencies in the search for resources in the remotest parts of the earth. Third, in recent decades paradigmatic shifts in society attitudes and 'cultural mediations' of resources have increasingly emphasized their environmental values and concern for the negative externalities of their exploitation, massively evidenced by climate warming, biodiversity loss, and large-scale degradation. Fourth, resource peripheries have become increasingly contested places around the globe and in effect center stage to battles over resource values and use. Fifth, resource-based MNCs remain among the biggest corporations in the world, and resource-based trade and foreign direct investment vitally important to global integration.

Although economic geography's reemerging interest in resources is evident from a variety of perspectives, this article is informed by an institutional approach (Bridge, 2008; Clapp, 1998; Essletzbichler, 2012). This approach is based on the reality that resources become rather than derive as 'gifts' of nature. Indeed, resources offer multiple (market and nonmarket) values causing use and abuse to invoke deeply felt public concerns and sentiments that require governments to pay special attention to the social acceptability of resource policies. The institutional reality is highlighted by property rights regimes that shape spatial patterns of resource use, conflicts driven by alternative value systems and power structures, and the integration of resources into the operations of corporations, value chains, and other institutions. In brief, the article broadly explores the relationships between location, organization, and markets of resource exploitation.

The remainder of the article progressively elaborates on the themes of natural resource governance and evolutionary and spatial dynamics, resource markets, and their coordination in value chains and cycles. The concluding sections focus on resource peripheries and their remapping, a global trend epitomized by complex resource conflicts driven by the intersection of competing economic, geopolitical, environmental, and cultural considerations. Given space limitations, the article is conceptual, refraining from discussing individual resource sectors nor engaging with ideas of human and capital resources. We also leave agriculture and resource-based tourism to their own articles.

Resources are extremely varied, often summarily classified as biotic or mineral, geographically as point and diffuse, and dynamically as renewable and nonrenewable depending upon whether the rate of depletion is less or more than the rate of replenishment. Resources typically require collection and some initial processing before private consumption or further industrial processing. Species of biotic resources such as forests

or fish vary enormously while even so-called resource commodities such as oil, coal, and lumber are differentiated in character with important implications for use. The measurement of the size and distribution of resources, long the subject of inquiry within economic geography, is not straightforward. Even visible resources such as trees are difficult to count even with modern-day technologies, discovery is an ongoing uncertain process, the viability of resources is enhanced and diminished by price and technological changes, substitution possibilities among resource inputs are considerable, and public policy can redefine resource values at the stroke of a pen. The Athabasca oil/tar sands, for example, had been used by indigenous people for several centuries to waterproof canoes and its recent massive commercial exploitation as a source of 'heavy' oil had to await technological innovations and oil price increases. Its continued expansion, perhaps even survival, now depends on public policy decisions in Canada and the United States that are seeking to balance wealth generating effects with environmental and cultural implications of its processing and distribution.

Ownership and Control of Resources (Property Rights)

Resource exploitation is rooted in the rules of governance and associated assignment of property rights, which, in general, are claims to benefits or income streams that imply exclusivity, security, and transferability. Exclusivity assigns sole rights of use to (resource) property, security is provided by law or social sanction, and transferability means that owners can sell or trade their property rights. Resource rights are held privately by individuals or corporations, in common by specified groups of people, and by governments; conversely 'open access' resources lack property rights. To crudely generalize, historically common property resources were widespread and underpinned different forms of aboriginal and peasant cultures that were rooted in tradition, custom, and the assignment of rights by elites. However, the onset of industrialization at the end of the eighteenth century, Polanyi's (1944) 'Great Transformation' toward market economies, privileged (legally enshrined) private resource property rights, often imposed at the expense of tradition and common property arrangements. This transformation involved enclosure movements in Europe and settler colonies in the New World, the former helping to stimulate the (massive) migration flows to the latter in the nineteenth century with the latter displacing indigenous populations through technology and military might, disease, and treaties (Diamond, 1997). The new property rights regime installed itself in an ad hoc, power-based manner. In Europe property rights maintained heredity titles, shaped by marriage arrangements and primogeniture (e.g., the UK's Royal family remain the largest private landowners), while European colonists stimulated settlement through various land grant systems (e.g., land given to railroad companies to fund their building and stimulate settlement).

Property rights assigned to land ownership, the template for property rights generally, can involve complex bundles of rights, obligations, and limits on resource extraction. The right to exploit resource above or below the ground can be allocated irrespective of land ownership and in the case where resources are mobile (e.g., oil, water, and fish), exploitation can be limited to prevent impacts outside the spatially designated area of property rights. Fundamentally, resource rights stipulate the right to withdrawal as set by institutional conditions that vary from place to place. These place-bound institutions are called resource regimes and refer to both the property rights regarding the use and transfer of resources and the (formal) de jure and (informal) *de facto* rules that govern these rights and their uses (Schlager and Ostrom, 1992; Vatn, 2007). The distribution of private rights can lead to direct conflict, such as when subsurface rights compromises access to surface rights. More generally, as illustrated by widespread environmental problems, private resource owners and users can have substantial indirect impacts on common property and open access resources.

Resource regimes are highly varied, and if the privatization of the commons is a relentless historical theme, there are many resources that remain publicly owned while privately controlled. For example, staking mineral rights have been used as a way of stimulating mineral exploration in remote areas in North America, allowing people to not only explore but also exploit mineral deposits on government or private land. During the 'Fordist' decades of the twentieth century resource exploitation escalated massively, and the so-called 'seven sisters' (oil MNCs) grew to dominate global petroleum reserves by the 1960s (O'Dell, 1963) by formalizing property rights within 'resource contracts' with host governments such as Saudi Arabia. These contracts or bargains were often quasiconfidential, but nevertheless took on a variety of forms that specified obligations, rights, and ownership conditions, the latter including outright privatization of resources but also more limited rights to resource use. In British Columbia, forests were initially sold into private ownership but this practice was stopped in 1912 following excessive speculation and overcutting. After 1947, to promote development throughout the province, the cutting rights of large forest tenures were leased or licensed over varying periods of time to large companies at relative low-stumpage or taxation levels in return for major capital investments in factories using local timber supplies and other (and evolving) obligations (Prudham, 2007).

For governments, the assignment and pricing of property rights are often controversial even when resources are primarily seen in industrial or economic growth terms. The nature, size, and temporal structure of royalties or taxes imposed on owners and/or controlling organizations of resource exploitation, along with the extent to which resource revenues should pay for existing public sector programs or be saved for use by future generations, are major issues. Important decisions also relate to the timing and speed of developments, and the extent and nature to which resource ownership or rights should be privatized among small firms, domestic champions, joint ventures, and MNCs. Thus the World Bank has been a major support of resource contracts with MNCs who they argue provide expertise, access to markets and finance, and abilities to promote development in remote areas. However, driven by fears over loss of domestic control, profits, and diversification opportunities, resource nationalism emerged as an important response as several developing countries, but also Canada, chose to return some resources to public control or at least establish champion domestic resource companies. For American MNCs

resource nationalism implied an 'obsolescing bargain' (Vernon, 1971). Indeed, in the contemporary oil sector, the biggest companies are now state-controlled, and several of the seven sisters have disappeared through acquisitions. The ownership of water resources has similarly become controversial as privatization is both seen as a way to promote efficient delivery and needless alienation of a gift of nature essential to life, and traditionally under public control (Bakker, 2005). Water use is also an issue in the spectacular expansion of oil shale fracking as a source of natural gas and oil that may threaten water tables in Dakota and other American states. The expansion has occurred on private farms that have no control over subsurface rights, unable to stop the fracking process by those who control these rights, often obtained decades ago.

Resource exploitation also occurs in the absence of property rights. In the coal mining region of Raniganj in India, for example, Lahiri-Dutt (2003) estimates that there are around 200 000 people involved in informal coal mining in which individuals collect coal from the tailings of wastes of the large mines and transport their coal, by foot or bicycle, to markets such as households and shops. If such behavior has social virtue levels of illegal poaching, for example, of endangered animals, fish, and trees, are massive, estimates (for 2009) placing the values between US$25 and 40 billion a year (Traffic, 2013: p. 8)

Resource Cycle Dynamics

Legal or illegal, embeddedness in nature, coupled with the limits to resource exploitation in any site, is the distinguishing basis for the evolutionary and spatial dynamics of resource exploitation. According to the resource cycle thesis, exploitation follows a life cycle curve based on discovery, slow initial growth, rapid growth, and a plateau effect as the region matures, followed by depletion and industrial decline (Clapp, 1998). Resource peripheries are exploited for the potential of new rich, low-cost resources – host governments encourage investment in social and economic infrastructure, while entrepreneurs and corporations compete to access the resource and provide services to resource producers. These actions compel labor to migrate for typically high-income jobs. The potential to large internal and external economies of scale is great and accompanying individual (marginal) increments such as new mines, pulp and paper mills, or oil drilling platforms are also large. Moreover, since the best, most accessible resources are typically extracted or harvested first, costs of exploitation typically increase. Meanwhile downward pressure on resource prices, for example, from increased competition, can imply a long-term cost-price squeeze for established operations (Freudenburg, 1992). In any given periphery, with depletion and competition from elsewhere, the resource cycle plateaus over time. While for nonrenewable resources, continued depletion inevitably leads to collapse, crises of deforestation, overfishing, and dustbowls indicate similar failures to renew renewable resources.

Geographically, resource cycles are constrained by nature and are powerful centrifugal forces in opening up remote 'new economic spaces.' Market prices in relation to production and transportation costs remain a fundamental point of departure for understanding the location dynamics of resource cycles (Hay, 1976). In conventional location theory terms, while transportation costs typically increase with distance from markets and the nature of transportation networks, processing costs are more irregular, dependent primarily upon size and quality of the resource and its ease of working. In this model, spatial pattern of mining reflects underlying cost structures and, for example, remote mines can operate when nearby mines are closed by substituting lower per capita processing costs for higher transportation costs. Indeed, the dispersal of mining (and other resource-based operations) operations to the distant corners of the globe is closely associated with increasing operating size that realize economies of scale, as well as investments in specialized transportation systems that reduce freight rates.

In practice, the nature of resource cycles in given peripheries are highly varied in duration, form, fluctuations, and intermittency. In the short run, operations can move in and out of production according to business cycle effects. Over the longer term, resource booms are reinforced by host governments seeking to encourage development by various incentives and favorable property rights conditions and by governments of major consuming countries or regions, such as the United States, Japan, EU, and now China seeking to secure low resources from a diversity of sources to ensure supply stability and pressure on prices (e.g., Gunton, 2003). Similarly, security interests underlying 'strategic resources' can help stimulate domestic supplies, as witnessed by recent ethanol, natural gas, and fracking booms in the United States (Kedron and Bagchi-Sen, 2011) or the search for alternatives as did Japan when China restricted its sales of rare earth minerals. Rich governments in particular have options to subsidize and prolong already mature resource cycles or, as happened in the rapid demise of the British coal industry in the 1980s, can chose to phase out operations for political as well as economic reasons. Notwithstanding the latter case, in general government policies that stimulate resource developments and encourage firms to seek secure supplies encourages more geographically diversified (and cyclical) patterns of exploitation than anticipated by cost considerations alone. Corporate rivalries in accessing resources reinforce this point (O'Dell, 1963). Further, the nature of resource cycles over the long run is highly varied, epitomized by technological changes that open up vast new resources, prolong the viability of existing operations or threaten them with obsolescence, and with possibilities for substitution. Cost reduction is not the only concern, as exemplified by public policy demand to develop renewable or less carbon-intensive sources of energy to replace conventional fossil fuels in homes, transportation, and business.

Resource Markets

The simplicity of competitive bidding and asking among many independent buyers and sellers for resources in some locations, such as in Japanese log auctions, is still evident (Reiffenstein and Hayter, 2006). Markets for most resources while retaining competitive price setting, however, no longer exist at a local basis and operate in an abstract manner. The prices for internationally traded, standardized commodities, are exchanged in highly competitive and liquid markets, but often in the form of

complex financial instruments (e.g., futures, contracts, swaps, and derivatives) (Zalik, 2010). The base price of fossil fuels, precious metals, and other minerals are all set on global markets, in the case of oil according to various regional and quality standards, such as West Texas Intermediate, North Sea Bent Crude Resource prices were once set in particular commodity exchanges, such as the Chicago Board of Trade, and then relayed around the globe, are increasingly set in electronic exchanges with instantaneous inputs from around the globe.

The viability of any resource exploitation must be measured against the prices set by these international markets, which react swiftly to political, economic, and technological changes and completely disregard production cost differences and any investments made by companies or countries. The relatively inexpensive exploitation of shale gas and oil is disrupting enormous investments and socioeconomic expectations in regions as diverse as Alberta and Nigeria. At the same time, many resource markets are strongly regulated at global, national, regional, and local levels. The Organization of Petroleum Exporting Countries (OPEC) has attempted to control its members export levels to maintain prices, local authorities have established environmental taxes, and Alberta's exports to the United States are sold at substantial discounts in part for quality reasons but also because of a lack of alternative markets and control over transfer prices by MNCs. In the timber trade, construction-grade Canadian lumber exports to the United States have faced tariff, export taxes, and quota limitations since the mid-1980s (Edenhoffer and Hayter, 2013a). Nationally and regionally the prices of utilities such as water and electricity are often set by bureaucracies or monitored closely by authorities with oversight. In addition, competition, land and labor costs, or other conditions may cause prices to vary somewhat from the global. A few commodities, such gravel or water, tend to be marketed more on a local or regional basis because of high-transportation costs.

Resource markets can be highly controversial, perhaps because of their derivation from nature with its connotations of public ownership and because of their role in providing essentials of life. In recent debates, these controversies have been especially intense when formerly public resources have been privatized. Within economic geography, these trends have been regarded as a neoliberalization or privatization of nature (Bridge and Jonas, 2002; Castree, 2008). Bakker (2010a,b), for example, has examined how water has been transformed from a natural, commonly held good by increasing marketization, that is, a shift from reliance on public provision to private provision, and allowing for predominantly locally governed resource to one infiltrated by global capital. Relatedly, agricultural commodities as well are becoming virtual water commodities as they embody the vast amount of water used in cultivation. Moreover, the marketization of ecosystem services (such as carbon sequestration, water retention, and soil formation), which although advocated by environmentalists, governments, and business as a means to rescue nature, have incurred unintended social and environmental consequences, such inequitable distribution of benefits and undervaluation of resources (Matulis, 2013; McAfee, 2012).

Carbon pricing is an emerging vital issue that usually imposes direct taxes on carbon produced or indirectly as a cap and trade system to quantify and internalize the environmental costs of green-house gas (GHG). Carbon markets especially target resource industries, and have been attempted in various jurisdictions but so far with uncertain, variable, and contentious effects at global, supranational, national, and regional levels (Bailey and Maresh, 2009; Bailey et al., 2011; Boyd, 2009; Boyd et al., 2011; Bumpus, 2011; Bumpus and Liverman, 2008; Ciscell, 2010; Demeritt, 2001; Gutiérrez, 2011; Knight, 2011; Lovell and Mackenzie, 2011; Robertson, 2011). Some of these regulations are perceived as a form of protection for domestic industries. For example, under present world trade rules, nations that have domestic GHG legislation have the right to impose tariffs on imports from jurisdictions that do not have this legislation. Such tariffs, already introduced by Japan and California and are anticipated in China, South Korea and for the United States as a whole, effectively reduce the returns of (foreign) resource suppliers. In California's case, while existing and proposed GHG tariffs occur on a wide range of resource products, in-state producers (including of heavy oil) are released from such taxes. In response to such trade protection, foreign resource peripheries need to reduce GHGs prior to export.

Value Chain Coordination of Markets

Although most commodities are priced at some point through competitive markets where there is reasonably symmetrical information among many buyers and sellers, these prices are influenced to a great degree by the internal and quasi-internal markets of global value chains (GVCs) in three ways. First and relating to the discussion of commodity markets, global and national resource industries are dominated by oligopolies and monopolies that have a large impact on the setting of prices. Indeed, antitrust (antimonopoly) laws were initiated to break Standard Oil control over petroleum prices in the late-nineteenth century, then the seven sisters effectively set a world price with its 'Gulf plus' agreement, which was superseded by OPEC's cartel.

Second, MNCs are powerful agents that organize GVCs or global production chains (GPNs) in terms of production, distribution, and recycling of resources. Within GVCs, the MNC and firms can exploit several opportunities to extract a fraction of the margin of the ultimate price of the commodity, or use the commodity as vehicle to market other goods and services. These GVCs are controlling resources such as petroleum or coal that after a relatively low level of refining/processing are marketed and consumed as a finished commodities that will be consumed by end users, Bridge (2008) has mapped out the contours of these global commodity chains using oil as an example. The stages of production are exploration, extraction, refining, distribution, consumption, and carbon capture. The backbone of this commodity chain is comprised of the major international oil companies, and more recently, the national oil companies such as Aramco, which integrate several stages of the chain. However, technical reasons for such integration only occurs at particular links in the chain, and at each stage there is room for competition and outsourcing; indeed, the major oil companies have increased outsourcing. In a finished commodity GVC, value capture, that is, the establishment of prices internal to the GVC, depends on the (1) benefits to internal integration from economies of scope and transaction

cost reductions; (2) demand–supply balance causing swings from consumer and to producer and back; (3) skills of firms at different stages of the production (e.g., by developing cost reducing technologies or innovative exploration methods); (4) trading on extraction rights between countries/owners and companies; and (5) imposition of carbon or other externality taxes. The oil GVC supplies a template for gas and coal-finished commodities although conditions from extraction to carbon sequestration differ significantly.

Third, GVCs incorporate myriad resources or embodied commodities (materials) such as hydrocarbons (plastics), metals, wood fibers, water, and other commodities in goods and services production. Interestingly, GVC analysis of manufactured goods (and industrial and economic geography generally) has largely ignored resource inputs, an increasingly untenable neglect because of environmental considerations. Resource geographers have focused primarily on sites of extraction and not delved into downstream concerns, while industrial geographers have simply assumed that commodity inputs were there. However, as ecological economists (Lovins et al., 1999) remind us, all manufactured capital depend on natural capital. Therein lies the rub because although goods and services cannot be produced without natural resource inputs, their value added within the GVC is minimal. Yet the logic of the GVC/GPN literature (Coe et al., 2008; Gereffi et al., 2005) is that the spatial distribution of commodity inputs is not only global, but value capture (and conversely value minimization) is negotiated through diverse institutions in different places. Moreover, the necessity to recover, recycle, and revalorize resources when products are discarded is recognized in the GVC/GNP literature, and reinforced by geographical contributions to analysis of industrial ecology (Deutz and Lyons, 2008; Gibbs et al., 2005; Lyons, 2007).

Urban Markets

Ultimately, demand for resources depends on urban markets, which directly and indirectly are the largest consumers of materials and fuels (Wackernagel and Rees, 1996). Global markets may set global prices, but it is the relative consumption, competition, and conservation of resources by cities that determines demand. Cities may appear dependent on resources, and may suffer from short-term scarcities, but because they can readily switch both location of supply and substitute most resources with other types of inputs, cities can act with high levels of impunity against resource scarcities. Moreover, urban systems are engines of innovation, constantly improving productivity and adding value to what they produce or changing what they produce, thereby improving levels of income in absolute and relative terms. On the other hand, the constant or relative value of resources has declined over time irrespective of increasing scarcity and nominally increasing costs of extraction, processing, and transportation. The terms of trade of the periphery are often in a constant, if irregular, state of decline.

Urban resource markets can be differentiated into public and private consumption. Governments or private companies provide infrastructure, buildings, and so on which consume large quantities of mineral, fuels, and water (concrete, asphalt, etc.), which are then consumed in a shared manner by consumers, companies, etc. Private consumption is when households and companies do not share the use of finished or embodied commodities (e.g., gasoline and cars as opposed to roads). The public and private realms are of course highly integrated, especially through the use of infrastructure and the vagaries of pricing and subsidizing the use of which (e.g., water, transportation and road subsidies, taxes, and tolls) bear upon how markets set prices for resources. Increasingly, cities are seen as the key to resource conservation and therefore reduced environmental impacts. Geographers are keenly involved in the reconfiguration of land use, infrastructure provision, and governance needed to transform the city's ecological shadow (Bulkeley, 2010, 2013). The recovery, recycling, and revalorizing of resources once treated as waste (metals, paper, plastics, etc.) exemplify how in addition to demand sinks, cities have become resource generators. In association, these changing demands and attitudes toward resources have important implications for resource peripheries.

Resource Peripheries

While resources are produced and consumed everywhere, resource peripheries gain their identity from significant dependence on resources for their well-being. Across the global economy, resource peripheries (and communities) have developed mainly to exploit and export resources for consumption in major markets (Auty, 2001; Hayter and Barnes, 1990).

Export-dependent resource peripheries are typically highly vulnerable to the fluctuations of the business cycle, moving in and out of production as demand (and price) rises and falls. In this regard, resource peripheries are the geographical equivalent of the marginal unit in mainstream economics, which is the last to be added and the first to be withdrawn in responding to, and 'settling down' price changes. For resource peripheries, this vulnerability to demand changes is powerfully reinforced by additional institutional forces that impose longer term booms and busts, each of which can be 'interrupted,' even masked, by short-term business cycle effects (Edenhoffer and Hayter, 2013a). Indeed, booming and busting is a widely proclaimed characteristic of export-driven resource peripheries that can be summarily explained with reference to resource cycle dynamics that incorporate the implications of depletion, technological change, and competition (Freudenburg, 1992; Clapp, 1998). These implications are further elaborated by considerations of geopolitics, corporate strategies, and host region development aspirations.

Typically, resource peripheries feature high levels of internal and external competition. In this regard, suggestions to add value to resources, differentiate production, and develop flexible specialized structures have helped mitigate competition (Reiffenstein et al., 2002; Patchell and Hayter, 1997). However, potentials in this regard seem limited, as attempts to add value and increase prices face resistance from cores, the policies of MNCs as well as market size limitations. Collusion among peripheries to control supply and prices also seems to have limited potentials, OPEC's example notwithstanding. Rather, as indicated by the current 'rush' in several jurisdictions to build massive new LNG plants, resource peripheries seek

competitive advantages through large-scale, low unit-cost production, and by penetrating booming markets as early as possible. In turn, such strategies ensure resource cycle effects. Admittedly, competition between new low cost and old high cost peripheries is not straightforward. Mature resource regions draw upon established capital and human resources, may develop more valuable products, and think up ways to reduce costs while the opening of new resource spaces costs requires major investments in productive capital, infrastructure and the hiring, training, and housing of workers.

The ability of governments in export-dependent resource peripheries to protect producers as they mature is limited by international trading rules and domestic market size. Such protection nevertheless occurs, including by rich core countries. Moreover, rich countries may cite security as well as social concerns in support of higher cost domestic operations that replace cheaper imports. In this regard, it is interesting to wonder why the United States and Western powers allowed rare earth minerals to become concentrated in China, given their evident vital importance in contemporary industrial processes. Rare earths, usually mined in very small quantities, have vital roles in a wide range of industrial processing and sophisticated green technology applications; for example, neodymium is used in wind turbines and lithium in batteries for electronic vehicles and other products. However, this dependence is changing.

For many resource peripheries and communities, the staple trap or curse is a haunting reality, as diversification potentials are limited by remoteness from markets, specialized infrastructures, ingrained export-based resource cultures, small population base, specialized labor skills, and so on (Watkins, 1963; Gunton, 2003). Resource corporations are also often highly conservative, locked-in to established attitudes, knowledge, technologies, and missions (Edenhoffer and Hayter, 2013b). Resource wealth has provided the basis for highly diversified, rich, urbanized economies (Walker, 2001). However, within in regions such as California, British Columbia, and Quebec there are resource peripheries and communities struggling to become more resilient (Markey et al., 2012; Polèse and Shearmur, 2006). For mature, booming, and new resource towns alike, however, plans for growth or revitalization can no longer think of resources solely in industrial terms.

Remapping Control

As revealed by the core-periphery dilemma, host countries and regions are vexed by the need to control their resource industries to enhance the welfare of its people. This struggle for control has undergone a remapping over the last few decades from a dyad between state and corporation to multifaceted power struggles among a diversity of local and global stakeholders. This remapping also reflects a shift from market to nonmarket valuation of resources.

In brief, in the evolution of development thinking in the 1950s and 1960s, resource peripheries were conceptualized as 'empty lands' within the formulation of export-based 'North American' models, in comparison 'European' development grew out of established societies (Thomas, 1969). At that time, and since, within the classic market valuation dyad, the role of MNCs in resource exploitation has been the principal lightening rod for debate. Different perspectives on this role are readily provided by Canadian and Norwegian approaches to promoting the oil industry. Thus in Norway, its oil resources in the North Sea have remained under public control, it has privileged a state-owned champion, and has favored high levels of taxation to generate wealth to be saved for future generations. Indeed, Norway's Heritage Fund had reached $664 billion by 2012, mainly invested off-shore to reduce Dutch Disease (currency inflation) problems and the interest on which can fund social programs permanently. Canada's approach is more short-term, encourages ownership and control by MNCs (and now state-owned companies from elsewhere), and emphasizes low taxation levels that mainly fund government programs now. Alberta, as Canada's main oil producer, has a modest heritage fund of around $16 billion. Even so, its oil fields, now dominated by the Athabasca oil/tar sands, have served as a major boost to the provincial and national economy by providing export income, demands for a wide range of goods and services, massive job opportunities, a major source of 'transfer payments' that are sent by the federal government to poorer provinces (in 2012 this meant all provinces but Alberta, BC, and Newfoundland), and if the necessary distribution systems are built potentially providing for domestic energy self-sufficiency and/or export diversification away from the United States.

It is interesting to recall that in the formulation of export-based models in which resource endowment provided the basis of competitive advantage, nature's nonindustrial benefits were largely tangential, recognized mainly in terms of amenity values. Meanwhile, the empty land assumption meant indigenous populations could be similarly ignored in the rich country (North American) model, or treated as 'inhibiting constraints' in the context of export-driven growth in poorer countries (Hirschman, 1958). These environmental and cultural blinkers can be accepted no longer. Over the past several decades environmental and indigenous peoples' voices have become increasingly insistent and resource policies have increasingly reflected their concerns. If these voices are related they are not the same, and are highly differentiated. In addition, albeit in decline, there are still a few subsistence economies located in peripheries in which resource harvesting is locally consumed. The trends are related: conservation areas are a response to the spread of resource-based production that continues to threaten surviving subsistence cultures but more broadly indigenous groups that are drawn from these cultures. Nevertheless, across the globe, environmental and aboriginal concerns are exerting a profound influence on resource peripheries, especially in relation to the once dominant emphasis on industrialization.

Moreover, in recent decades, as an important feature of contemporary globalization, urban centers are no longer simply demanding resources from the periphery, but are expecting peripheries to conserve resources for regional, national, and even global ecological benefits (Zimmerer, 2006). These demands are vocalized through many environmental nongovernment organizations (ENGOs) such as Greenpeace and WWF. Sometimes the ENGOs act in concert with indigenous and local people, but sometimes not, and their urban idealizations of the periphery can also conflict with the expectations of local labor industry and community

interests in rich and poor countries (Hayter and Soyez, 1996; Nietschmann, 1997).

The conflicts and compromises arising from the confrontation between not only the host-corporation dyad, but also demands for indigenous and environmental rights are causing remapping of resource peripheries. This reterritorization is rooted in a redefinition of property rights away from vested industrial interests in favor of hitherto marginalized actors (Brogden and Greenburg, 2003; Clapp, 2005; Hayter, 2003). However, remapping processes are inherently normative and in practice have been marked by considerable conflict with 'resource wars,' metaphorical and real, occurring around the world. Analytically, these conflicts have been interpreted by a four-legged stakeholder model that stresses interactions among differing industrial, political, environmental, and cultural institutions (Affolderbach et al., 2012; Hayter et al., 2003) and by a related three-legged model framed by corporate, community, and government actors with ENGOs as a fourth estate (Ballard and Banks, 2003). With especial reference to ENGOs, Affolderbach (2012) interpreted forestry conflicts in terms of environmental bargaining between ENGOs and key decision-makers while Affolderbach et al. (2012) reveal the importance of 'boundary organizations' that involve scientific inputs that are acceptable to all parties, in resolving such disputes.

Within resource peripheries around the world, in rich and poor countries alike, aboriginal rights have become increasingly more high profile, symbolized on a global scale by the 'UN Declaration on the Rights of Indigenous Peoples' in 2007. While often joining with ENGOs to oppose large-scale industrialization they are not the same, especially when the latter seek to limit control by indigenous peoples over 'their' resources. Whether indigenous peoples are seeking to stop resource industrialization to protect traditional ways of life or become more significant stakeholders in resource wealth generation in several new world economies, such as Australia, Canada, and New Zealand, and developing countries such as Brazil and Indonesia resource contracts are having to take into account aboriginal concerns far more seriously than in the past.

From industry's perspective, the proliferation of resource wars are not simply a passing annoyance, even if in the 1980s this was how they were often perceived, but have encouraged attitudes and policies that are redefining the global role of resource peripheries in much broader terms than imagined in original export-based theories. This remapping is most evident in the considerable expansion of conservation areas from 2 million km in 1965 to 14 million km in 2006, much located in the Boreal forest region, along with an expansion of protected marine areas (Affolderbach et al., 2012; Zimmerer, 2006). In these conservation areas, resource supplies to industry is either stopped or greatly modified. Further, a battery of environmental legislation has required reductions in air and water pollution that have significant costs especially on existing resource industries that have been forced to modify long-established practices. While new projects can often, more cheaply incorporate state of the art technology from start-up, they must embrace costly, time-consuming environmental impact assessment in their planning, even if such procedures are highly controversial. In addition, various forms of certification that apply across industries, such as ISO 1400, and to specific industries, such as forest certification (Stringer, 2006), are providing increasingly strict vigilance on firms and supply chains that have increasing recognition among consumers.

Conclusion

Resource geography shares economic geography emphases on space–place relations, global–local dynamics, examination of the role and diversity of institutions, and evaluation of the positive and negative impacts of markets. It cannot be said, however, that resource geography informs economic geography to a great extent, a surprising phenomenon given the size of the resource sector, its indispensability and integration with the rest of the economy, and the linkage with geography's environmental concerns. The remapping of the resource sector, however, is an on-the-ground reality that declares this neglect is untenable By more fully incorporating resources into its theorizing mainstream, economic geography will not only be returning to its roots (Zimmerman, 1933), but also strengthen its explanatory power.

Respiratory Disorders: Psychosocial Aspects

Andreas von Leupoldt, University of Leuven, Leuven, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Asthma and chronic obstructive pulmonary disease (COPD) are prevalent respiratory diseases and are associated with great individual and socioeconomic burden. Psychosocial aspects play an important role in the course and management of these diseases. This article provides an overview of important psychological and social aspects in asthma and COPD and how these are related to morbidity. In addition, respective treatment approaches that include psychosocial aspects are presented and the urgent need for future research in this area is emphasized.

Introduction

Asthma and chronic obstructive pulmonary disease (COPD) are not only the most prevalent respiratory diseases, but also belong to the most common chronic diseases in general. For example, asthma is the most common chronic disease in children whereas COPD is the fifth-leading cause of death worldwide (Global Initiative for Asthma (GINA, 2012); Global Initiative for Chronic Obstructive Lung Disease (GOLD, 2013)). Both diseases are characterized by chronic inflammatory intrapulmonary processes, which lead to reduced lung function due to bronchoconstriction, mucus production, and/or permanent remodeling and damage of lung tissues. Resulting symptoms are episodes of breathlessness, cough, and wheezing, which can be accompanied by various other comorbid symptoms, especially in COPD (GINA, 2012; GOLD, 2013). Although there is some overlap between asthma and COPD, both diseases have distinct characteristics regarding onset, pathophysiological mechanisms, and treatment. For example, whereas asthma is often diagnosed in childhood with symptoms usually being present episodically, COPD is typically diagnosed in older individuals, often after a long history of heavy smoking, with symptoms usually being chronically present. Both diseases require close monitoring of symptoms and regular medication intake including short- or long-acting bronchodilators and anti-inflammatory corticosteroids, preferably administered by inhalation. Asthma and COPD are associated with considerable individual as well as socioeconomic burden. In addition to prominent physiological symptoms, psychosocial aspects play an important role in the course and management of these diseases. However, compared to other chronic diseases, psychosocial aspects in asthma and COPD have not received the same level of systematic research activity or public interest. Therefore, this article provides an overview of important psychological and social aspects in asthma and COPD, on potential links with morbidity as well as on respective treatment approaches. Moreover, needs for future research in this area are pointed out.

Comorbid Psychological Symptoms in Asthma and COPD

Comorbid psychological symptoms, especially anxiety and depression, are highly prevalent in patients with asthma and COPD. In asthma patients, prevalence rates for anxiety and depression of up to 45 and 41%, respectively, have been reported for some inner-city samples (Feldman et al., 2005). In COPD patients, a meta-analysis revealed prevalence rates for anxiety and depression of 36 and 40%, respectively (Yohannes et al., 2000), which can reach up to 80% in specific subgroups of patients.

A substantial number of studies have demonstrated that comorbid psychological symptoms are associated with a less favorable course of asthma and COPD, respectively. This includes more frequent exacerbations, longer and more frequent hospitalizations, increased inflammatory status, persistent smoking, increased symptom burden, inappropriate medication use, worsened physical and social functioning, decreased quality of life, reduced activity levels, less favorable outcome of pulmonary rehabilitation, and even increased mortality rates (Ritz et al., 2013; von Leupoldt et al., 2012; von Leupoldt and Kenn, 2013). These negative relationships seem particularly prominent in severe and not well-controlled forms of the diseases, but are already of importance in milder forms. Not surprisingly, comorbid psychological symptoms were found to be related to increased health-care costs in patients with asthma and COPD. For example, a large retrospective cohort study estimated that the average annual all-cause cost per COPD patient was $28.961 for those with comorbid depression and anxiety compared with $22.512 for those without these comorbidities (Dalal et al., 2011). Notably, psychological comorbidities remain undetected and untreated in more than 50 and 70% of patients with asthma and COPD, respectively (Katon et al., 2006; Kunik et al., 2005). Therefore, the early detection and adequate treatment of comorbid psychological symptoms in patients with asthma and COPD remains a major clinical target requiring intensified research on the development and implementation of respective strategies.

While the exact reasons for the high prevalence of comorbid psychological symptoms in patients with asthma and COPD are largely unknown, they are most likely multifactorial with considerable interindividual variability. Some findings suggest that the high burden associated with these chronic diseases including activity limitations and/or repeated experiences with threatening episodes of breathlessness is responsible for the later development of psychological comorbidities, especially in patients who tend to overinterpret bodily sensations (Livermore et al., 2010). Longitudinal data in patients with

asthma and COPD support this view by showing that a diagnosis of asthma and COPD predicted the later onset of symptoms of anxiety or depression, respectively (Hasler et al., 2005; Schneider et al., 2010). Nevertheless, some of these studies also found that preexisting symptoms of anxiety and depression were associated with the subsequent onset of asthma or COPD (Hasler et al., 2005; Scott et al., 2008; Schneider et al., 2010), suggesting a reciprocal association between these respiratory and mental disorders. In addition, it might be speculated that a common third factor is underlying both the development of the respiratory disease and psychological symptoms, for example, smoking behavior, systemic inflammatory processes, or genetic influences (Mrazek, 2003; Van Lieshout et al., 2009; Goodwin et al., 2012). The limited availability of respective studies necessitates future multidisciplinary research activities to better understand and treat these high prevalence rates of psychological symptoms in patients with asthma and COPD.

Social Aspects in Asthma and COPD

Social aspects including cultural, environmental, and family factors have been demonstrated to greatly impact respiratory diseases, especially asthma (Ritz et al., 2013). For example, minority populations in the USA including African-Americans and Puerto Ricans have not only higher prevalence rates of asthma than those with European ancestry, but also show lower asthma control, fewer prescriptions of inhaled corticosteroids, more frequent hospitalizations, and emergency department visits as well as more fatal asthma attacks (Leong et al., 2012). Moreover, living conditions in urban environments can contribute to higher asthma morbidity and mortality due to several factors. These include increased indoor allergen exposure, air pollution, and viral infection, but also social stressors such as poverty, high crime rates, domestic violence, and disrupted family constellations (Wright and Subramanian, 2007).

Family variables play a critical role in asthma, particularly in children with asthma. Factors such as the parent–child relationship, parenting difficulties, family conflicts, and family organization have all been demonstrated to impact asthma management and clinical outcomes (Ritz et al., 2013). Family factors are already of importance during the prenatal development. For example, high maternal stress levels are associated with the later onset of asthma and atopy in the offspring (Wright, 2011).

In patients with COPD, research on social factors is still at an early stage. Some findings suggest that supportive social relationships are associated with a more favorable course of disease including lower hospital readmission rates, breathlessness, or depressive symptoms as well as improved exercise tolerance and survival rates, although conflicting results have also been reported (Kaplan and Ries, 2002; von Leupoldt et al., 2012). In addition, further aspects such as peer group attitudes and behavior, dynamics of self-evaluation, stigmatization of asthma or COPD as a disease as well as social comparison processes have been shown to affect disease outcomes (Ritz et al., 2013; Petersen et al., 2012). Notably, some studies show that not only patients with COPD but also their partners have reduced quality of life and elevated symptoms of anxiety and depression, which might interact with the patients' level of symptoms (von Leupoldt et al., 2012). These findings indicate that partners of COPD patients can be substantially affected by the disease of their ill partners, hence suggesting a need for interventions that include partners. In general, future research is needed to refine our understanding on how social aspects impact on asthma and especially on COPD and how these aspects could be used to improve their treatment.

Links between Psychosocial Aspects and Disease Processes

Both direct physiological and indirect behavioral pathways as well as their interactions can potentially link psychosocial aspects with pathophysiological processes in asthma and COPD and contribute to worse or improved course of disease.

Evidence for direct pathways comes mostly from animal and human studies on asthma, which demonstrated direct psychosocial influences on the pulmonary system, on autonomic and endocrine regulation, gene expression as well as on inflammatory and immune processes (Ritz et al., 2013). For example, negative affective states or stress lead to vagally mediated bronchoconstriction (Ritz et al., 2010) and increased airway inflammatory responses in patients with asthma (Chen et al., 2010). Elevated stress levels during pregnancy have been suggested to alter the normal development of organ systems such as immune and respiratory system and to prime the neuroendocrine, autonomic, and immune systems of the offspring toward the later development of allergic diseases including asthma (Wright, 2011). Emerging neuroimaging studies in healthy individuals illustrate that negative affect impacts on the neural processing of respiratory sensations (von Leupoldt et al., 2013), presumably via brain areas with shared relevance for both emotion processing and the processing of respiratory symptoms (e.g., insular cortex, anterior cingulate cortex, amygdala) (Davenport and Vovk, 2009). First findings suggest that patients with asthma might show disease-specific patterns in neural activation and brain structures, which might be related to disease duration, near-fatal attacks, or airway and inflammatory responses (von Leupoldt et al., 2013; Ritz et al., 2013).

Indirect pathways linking psychosocial factors and morbidity in asthma and COPD are through self-management and health behaviors. Both diseases require constant symptom monitoring, regular medication intake, and timely initialization of adequate actions in case of disease exacerbations, which necessitate various behavioral skills of the patients. Results from several studies suggest that negative clinical outcomes in asthma and COPD are related to chronically poor medication adherence, insufficient inhaler technique, reduced levels of physical activity, and unwillingness to quit smoking (Ritz et al., 2013; von Leupoldt et al., 2012; von Leupoldt and Kenn, 2013). These behaviors are greatly influenced by patients' subjective beliefs about the disease, key symptoms, and treatment (side)effects. For example, fearful overinterpretations of breathlessness and/or beliefs about effects of exercise have been shown to be associated with reduced exercise performance, lower quality of life, and higher breathlessness ratings in COPD patients (Janssens et al., 2011). The presence of more general

comorbid psychological symptoms such as anxiety and depression presumably amplifies these unfavorable associations. For example, in patients with COPD, depression was found to be related to reduced medication adherence (Khdour et al., 2012). Moreover, the subjective perception of respiratory symptoms can greatly impact on the course of respiratory diseases via subsequent health behaviors. In this regard, both over- and underperception of breathlessness have been linked to morbidity and mortality, especially in asthma, due to either exaggerated (self)treatments and activity avoidance or due to delayed and insufficient treatments (Ritz et al., 2013; von Leupoldt et al., 2012; von Leupoldt and Kenn, 2013). A variety of psychosocial aspects might further impact on respiratory symptom perception including negative affect, focus of attention, learning, context, and social variables (Janssens et al., 2009; von Leupoldt et al., 2013).

Although more refined future research is certainly required, it seems that many social aspects likely operate via indirect pathways. High levels of social support and beneficial family and environmental constellations have been suggested to be effective in absorbing distress caused by the deleterious consequences of the illness, in enhancing perceived self-efficacy, and/or in promoting positive adaptive health behaviors including treatment adherence (von Leupoldt et al., 2012). For example, a more favorable level of family routines has been shown to be associated with decreased inflammatory status in young asthma patients, which was mediated by its impact on medication use (Schreier and Chen, 2010). Notably, the various levels of the social environment may affect respiratory disease morbidity through both direct and indirect pathways in the same patients. In this regard, Chen and co-workers (Chen et al., 2007) demonstrated in the same sample of adolescent asthma patients that family factors affected the adolescents' asthma via direct physiologic changes (inflammatory status), whereas community factors operated via indirect behavioral pathways (smoking behavior). However, intensified future research efforts on both direct and indirect pathways in patients with asthma and especially in patients with COPD are necessary in order to improve our understanding of the multiple systems involved and their impact.

Interventions Including Psychosocial Aspects in Asthma and COPD

Effective management and treatment of asthma and COPD aims at several goals, including symptom relief, prevention of disease progression/inflammation, improvement of activity/exercise levels, health status, and quality of life as well as prevention and treatment of complications and exacerbations (GINA, 2012; GOLD, 2013). Patients with asthma and COPD need to be treated by a physician, preferably with specific pulmonary training. Regular intake of usually inhaled bronchodilators and anti-inflammatory corticosteroids forms the mainstay of treatment, often accompanied by further medications. However, many aspects of these conditions necessitate a more comprehensive treatment approach according to the biopsychosocial model of disease, which requires a multidisciplinary approach combining various forms of treatment. These have to be tailored to individual patient's needs and should continuously be monitored (GINA, 2012; GOLD, 2013). Ideally, asthma and COPD care should be performed by a multidisciplinary team including physicians, nurses, physiotherapists, exercise physiologists, kinesiologists, occupational therapists, dietitians, social workers, mental health specialists, behavior nurse therapists, clinical psychologists, or liaison psychiatrists. In particular, behavioral medicine approaches offer a variety of relevant techniques and interventions that can be effective in alleviating the burden of asthma and COPD by addressing psychosocial aspects and by supporting important behavioral change in patients (Ritz et al., 2013; von Leupoldt et al., 2012). These interventions are often based on elements of cognitive-behavioral therapy extended by additional disease-specific elements such as behavioral activation, skill-building exercises, cognitive restructuring, psycho-education, exposure to feared situations, problem-solving techniques, thought stopping, self-instructional training, breathing trainings as well as nonspecific relaxation and stress management techniques or biofeedback trainings. Most of the techniques listed below are part of comprehensive treatment programs (e.g., pulmonary rehabilitation) or used in various combinations, which makes it often difficult to evaluate their distinct individual effects.

Self-management and patient education programs play an important role in the treatment of asthma and COPD and are recommended core components of pulmonary rehabilitation. Ideally, the character of these programs is interactive and focused on the teaching of self-management skills, emphasizing illness control through modifications of patients' health behavior. Typical components include the pathophysiology of lung disease, proper use of medication, benefits of exercise and physical activities, irritant avoidance/smoking cessation, prevention and early treatment of exacerbations, coping with the disease, control of negative affect, and breathing strategies (Ritz et al., 2013; von Leupoldt et al., 2012). Positive effects of self-management and patient education programs have been demonstrated in patients with asthma and COPD, including improvements in hospitalizations, quality of life, symptoms, and exercise capacity. However, future randomized controlled trials with long-term follow-ups are needed to develop clear recommendations regarding the form and specific contents of these programs. An interesting alternative to conventional programs might be programs using new media such as Internet, mobile phones, and smart phones in which patients can participate from home.

Recommended pulmonary rehabilitation programs entail comprehensive interventions, which can be delivered in inpatient or outpatient settings, usually in a group format. A large body of evidence illustrates the beneficial effects of pulmonary rehabilitation in patients with asthma and COPD including improvements in exercise capacity, symptoms, quality of life, hospitalizations, and negative affect (Spruit et al., 2013). Duration and components of pulmonary rehabilitation vary between programs. In addition to monitoring and optimization of pharmacological treatments, the common elements of these programs include exercise training, self-management and patient education, behavioral training, nutrition counseling, psychosocial support, smoking cessation support, breathing therapy, and respiratory muscle training (Spruit et al., 2013; von Leupoldt et al., 2012). The optimal duration of these programs and the most effective mixture of implemented

interventions remain to be established, but some evidence suggests that longer programs compared to shorter ones are more effective. Because benefits achieved during pulmonary rehabilitation wane after completion, intensified research efforts are necessary in order to improve the maintenance of these benefits once patients have completed these programs.

In general, exercise training is recommended for most patients with asthma and COPD and underlines the need for long-term behavior change. Documented benefits include improvements in cardiopulmonary fitness, skeletal muscle function, ventilation, symptoms, and quality of life (Spruit et al., 2013). Training elements vary considerably between programs and include among others lower extremity exercise (e.g., stationary cycle ergometer, walking) and upper extremity exercise (e.g., arm cycle ergometer, free weights). Training at higher exercise intensity seems to be associated with greater physiological benefits than lower-intensity training and a combination of endurance and strength training is probably the best strategy to improve peripheral muscle function. In many patients, bronchodilator therapy is given prior to exercise to reduce exercise-induced bronchoconstriction and breathlessness and to improve exercise tolerance.

Tobacco smoke is a main risk factor for the development and/or poor prognosis of respiratory diseases, especially in COPD. However, many patients continue to smoke, rendering smoking a major target for behavioral interventions (GINA, 2012; GOLD, 2013). Smoking cessation has been shown to improve lung function, symptoms, exacerbations, and mortality rates (Scanlon et al., 2000). Several interventions are available to motivate and support patients to quit smoking, often as part of comprehensive treatment programs such as self-management and patient education or pulmonary rehabilitation. These range from low-intensity interventions (e.g., brief advice by physicians, self-help materials, telephone counseling) to more-intensive and effective interventions (e.g., group counseling) (Ritz et al., 2013; von Leupoldt et al., 2012). Recent guidelines recommend the combination of psychosocial interventions and pharmacotherapy (e.g., nicotine replacement therapy) to support smoking cessation in patients with COPD (GOLD, 2013). However, typical success rates are usually poor and underline the urgent need for improved interventions aimed at supporting smoking cessation in patients with asthma and COPD.

Respiratory muscle weakness is often observed in respiratory diseases and contributes to blood gas anomalies, breathlessness, and reduced exercise performance. Inspiratory muscle training is aimed at increasing inspiratory muscle strength, usually by having patients breathe through defined resistances. Respective trainings vary with respect to frequency, duration, and type of resistances used, but continuous training in everyday life is mandatory to maintain achieved benefits. In patients with COPD, beneficial effects include improvements in inspiratory muscle strength and endurance, functional exercise capacity, symptoms, and quality of life (von Leupoldt et al., 2012). Future well-controlled studies are needed to examine whether similar effects can be achieved in patients with asthma (Silva et al., 2013).

Breathing training includes several controlled breathing exercises aimed at improving different pathophysiological aspects of lung diseases, such as reducing lung hyperinflation and improving regional ventilation, gas exchange, and thoracoabdominal coordination. Prominent examples are pursed-lip breathing, active expiration, and body positioning, which should be tailored to individual patient's needs. Recent studies demonstrated improvements in quality of life, mood, and symptoms by some of these exercises in patients with asthma and COPD (Ritz et al., 2013; von Leupoldt et al., 2012). However, future controlled trials are necessary in order to better understand which specific variant of breathing training is effective in which subgroup of patients.

The negative effects of anxiety and depression in patients with asthma and COPD necessitate adequate treatment, for example, with psychotherapeutic interventions. These are usually performed in groups and are based on techniques of cognitive-behavioral therapy extended by additional elements. Respective interventions include – among other elements – cognitive restructuring, mindfulness-based interventions, behavioral activation, skill-building exercises, psychoeducation, and exposure to feared situations. The duration of reported interventions greatly varies ranging from a single 2-h meeting up to programs lasting several weeks. Recent studies have shown some promising anxiolytic or antidepressant effects and improvements in quality of life, functional capacity, and hospitalizations in patients with asthma and COPD (Ritz et al., 2013; von Leupoldt et al., 2012). A small number of findings suggest some positive effects of family therapy for the management of asthma in children. These family therapy programs for asthma most likely do not only address emotional aspects of the family interaction, but also more general asthma management skills and their optimal implementation in the family constellation. In general, more and larger randomized controlled trials are necessary to draw definite conclusions about the beneficial effects of certain psychotherapeutic techniques for specific subpopulations of patients with asthma and COPD (i.e., differential indication), and the required duration and frequency of these treatments. In addition, the high psychological burden in partners or family members of patients with asthma and COPD requires intensified research activities on respective interventions.

A variety of further techniques targeting psychosocial aspects have been examined in recent years in patients with asthma and COPD including symptom perception training, relaxation training, biofeedback training, yoga therapy, singing training, and dietary interventions (Ritz et al., 2013; von Leupoldt et al., 2012). However, although promising effects were observed in some studies, the overall picture is that of mixed results in too few studies, which requires further randomized controlled studies on these as well as innovative new interventions. For example, the use of new media such as the Internet and smart phones might provide valuable options for existing as well as new forms of interventions.

Summary

Various psychological and social aspects have been demonstrated to play an important role in asthma and COPD. Both direct physiological and indirect behavioral pathways link psychosocial aspects with pathophysiological processes in these respiratory diseases. However, there is a considerable

need for further multidisciplinary research on these mechanisms and their specific impact on the course and management of asthma and COPD. Several interventions in asthma and COPD include psychosocial elements. While the beneficial effects of some interventions such as pulmonary rehabilitation and self-management programs are already established, distinct components of these interventions need further elaboration. Preliminary findings on other interventions are often encouraging, but require future randomized controlled studies in order to recommend their regular use. Moreover, additional research on the optimal transfer of beneficial treatment effects in clinical settings into long-lasting improvements in the everyday life of patients with asthma and COPD is necessary. In this context, the use of new media might be valuable, but requires further evaluation.

Responsibility in Social Work

Viviene E Cree, The University of Edinburgh, Edinburgh, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Responsibility is central to social work wherever it is practiced in the world, and yet it is a concept that is most often taken-for-granted, rather than afforded serious examination. This article argues that the idea of responsibility must be interrogated both vertically and horizontally, if we are to make sense of the complex dilemmas and contradictions at the heart of social work practice. The article concludes that social workers have particular responsibility to themselves, to others, and to the world in which people live by virtue of social work's unique role.

Introduction

A child cries, alone and hungry. An older person collapses in the street. A convicted sex offender commits suicide. Who is responsible? Social workers are the professional group most likely to be pilloried for doing too much or doing too little, accused of not dealing adequately with risk and for failing to prevent harm, "damned if they do and damned if they don't" (Cree, 2013). And yet the task of social worker is to take responsibility for those who are unable or unwilling to take care of themselves. Social workers are located between the individual and society, negotiating and at times, in conflict with both (Cree, 1995). This suggests that social work is, then, by its very nature, a 'responsible' profession.

This article will begin by offering a dictionary definition of responsibility, arguing that this must be understood in its historical, social, and cultural context. Responsibility is not a concept that is agreed by everyone across time. Instead, accepted ideas of what it is to be responsible have changed over the years and are currently understood differently in developing and developed world contexts. This does not mean that it has no specific meaning for social work. On the contrary, social work relies on a particular interpretation of responsibility that is enshrined in legislation, in its international definition, and its codes of ethics. These will be explored as this article unfolds.

The article will first introduce different types of responsibility vertically, exploring, in turn, ideas of individual, family, social, and collective responsibility. It will then examine responsibility horizontally, giving attention to moral and professional responsibility, that is, the kinds of responsibility that run throughout social work practice wherever it is located. All ways of thinking about responsibility reflect crosscutting themes of rights, risk, duty, and blame. These come together in a final discussion that turns to conclusions and implications for the future.

Defining Responsibility

The Oxford English Dictionary (2012) definition of responsibility is as follows:

1. having a duty to deal with something or of having control over someone;
2. being accountable or blamed for something;
3. the opportunity or ability to act independently and take decisions without authorization.

This definition throws up a number of key ideas, including 'duty,' 'control,' 'blame,' 'independence.' All are central to a wider examination of responsibility, both vertically and horizontally, and all are open to negotiation and likely to change over time and in different contexts and countries.

Vertical Strands

Individual Responsibility

At its most simple, responsibility is concerned with individual or personal responsibility: individuals are responsible for themselves, their successes and failures. People also may hold responsibility for the action (or inaction) of others who, by virtue of their age and vulnerability, need another person to take some responsibility for them (including very young and very old family members, those who are sick or disabled and in need of care).

This understanding of responsibility is filled with historical resonance. From the seventeenth century onward, ideas of individualism and liberalism were at the heart of political, economic, and social life in the then industrializing world. 'Laissez-faire' principles maintained that the market should be free to regulate itself; that government intervention in economics and in society would do more harm than good. At the same time, it was believed that anything was possible for those who worked hard and showed initiative; 'heaven helps those who help themselves' was the familiar mantra of the day. Self-help was seen as the best way forward, and any assistance given to needy individuals should be that which encouraged independence and individual responsibility, not dependence and sloth (Fraser, 2009). The idea of individual responsibility is illustrated in the workings of the UK Poor Law (Cree and Myers, 2008). Those in need were classified into two groups: the 'deserving' and 'undeserving' poor; the deserving poor were those who were prepared to take responsibility and act to improve their situation, while the undeserving poor were characterized as idle, feckless, and irresponsible. When the Charity Organisation Society was formed toward the end of the nineteenth century, the principles of 'scientific charity' again highlighted the value of individual responsibility (Seed, 1973: 17).

A very similar presentation of responsibility is found across the world, demonstrated in the popular slogan, "If you give a man a fish you feed him for a day. If you teach a man

to fish you feed him for a lifetime" (Kiewra, 2010: 78). Encouraging individual responsibility is not, however, always positive, for the individual or society. Individualism may bring with it selfishness, acquisitiveness, and a lack of concern for others. It may also encourage a culture of blame. Webb points out that "although we are supposed to increasingly take responsibility for our own actions, there is plenty of evidence suggesting we wish to point the finger of blame elsewhere" (2006: 12). He cites obesity as an example of this; people prefer to blame the 'fast food' industry for our obese society, rather than confront the more difficult issue of individual choices in eating habits. They are also quick to deny any personal responsibility for 'bad' things such as atrocities or torture. Individuals often prefer to acquiesce, obey, and deny responsibility, rather than face up to the challenge of expressing disagreement with others (Cohen, 2000).

Ideas of individual responsibility infuse two current strands within social work: the idea of 'personalization' and the notion of 'responsivity.' Personalization is a policy initiative that emerged within social care. The not-so-radical idea is that people should be responsible for their own support services, able to determine and manage their own care, rather than fitting in with existing models of service provision. This, of course, reflects notions of individualism discussed above. It also owes allegiance to the idea of 'client self-determination,' which came out of casework practice in the 1940s and 1950s (Biestek, 1951) as well as pointing to current ideas about individual rights, illustrated in both Human Rights and Disability Discrimination legislation. Personalization has been viewed by some commentators (for example, Ferguson, 2007; Lymbery, 2012) as a double-edged sword: although it is, in principle, a positive development for service users, personalization moves responsibility for care from service providers to service users, allowing the state to abdicate responsibility and, at the same time, transferring any risks associated with this; the market, meanwhile, is free to dominate the supply of care services (Cree, 2009).

Responsivity also draws on ideas of individual responsibility. The term first emerged in criminal justice literature in North America (Andrews et al., 1990). The responsivity principle suggests that the delivery of programmes of intervention should be matched to the characteristics of offenders and their needs; the relationship between the offender and his/her social worker or probation officer is identified as central to this (Whyte, 2009: 62). Proponents argue that variations in reoffending can be related principally to risk, need, and responsivity (Andrews et al., 1990). Critics, however, assert that this is oversimplistic; that programmes must take account of social and cultural contexts and must build on offenders' strengths, rather than focusing only on their weaknesses and problems (Whyte, 2009). This is a reminder that focusing on the individual and on individual responsibility is not enough; rather that issues of society and structure remain of major importance.

Family Responsibility

An idea that is as old as the idea of individual responsibility is that of family responsibility: the family is here held to be the first port of call for anyone in need. An illustration is found in the early Elizabethan Poor Laws in the UK, which stated:

> It should be the duty of the father, grandfather, mother, grandmother, husband or child of a poor, old, blind, lame or impotent person, or other poor person, not able to work, if possessed of sufficient means, to relieve and maintain that person.

When people later came together to campaign for the establishment of welfare services in the UK in the early years of the twentieth century, critics argued that such provision would undermine family responsibility and make it too easy for people to abdicate their responsibilities for each other (Fraser, 2009), thus demonstrating again the close connection between ideas of individual and family responsibility.

The principle of the paramountcy of family responsibility is one that runs through all social welfare today, wherever it exists in the world. Charters that uphold individual rights are commonly prefaced by ideas of family duty. For example, the UN Convention of the Rights of the Child (1989) and the African Charter on the Rights and Welfare of the Child (1990) both state that parents have primary responsibility for the upbringing of their children, although, interestingly, the African charter suggests that children have responsibilities too, to their families and communities:

> Every child shall have responsibilities towards his family and society, the State and other legally recognized communities and the international community (Article 31).

The idea of family responsibility is also central to world religions. For example, an Islamic prophet wrote: "Every one of you (people) is a shepherd. And every one is responsible for whatever falls under his responsibility. A man is like a shepherd of his own family, and he is responsible for them."

The issue of family responsibility is one that, traditionally, has had particular meaning for women. Numerous feminist studies from the 1970s onward pointed out that taking responsibility for family members usually falls to women. Graham (1983) went so far as to argue that caring was a fundamental part of women's self-identity. More recently, it has been acknowledged that issues such as 'race'/ethnicity and social class are also significant; it is often the labor of black and working-class women that allows middle-class parents to work outside the home (Graham, 2007). Research has also drawn attention to the reality that family responsibility is not, in practice, held only by parents. Grandparents and young people are also strongly implicated in family care (Gray, 2005; Cass, 2007).

Radical voices in social work in the twenty-first century have returned to the potential for misuse of the notion of family responsibility. It is argued that foregrounding family responsibility as a policy initiative allows the state and professionals to blame victims for their plight, meanwhile the structural failings of society remain obscured (see Ferguson and Woodward, 2009).

Social Responsibility

The notion of social responsibility, like that of individual and family responsibility, is an ancient one. Within the

Judeo-Christian tradition, the idea that human beings are responsible for each other is found in the parable of the "Good Samaritan" (Luke 10: 29–37). This tells the story of a traveler who is beaten and robbed; the person who rescues him is not the priest or a member of his own social group but a Samaritan (Samaritans were despised by Jewish people). The parable draws us to reflect on "who is my neighbour?" The Qu'ran similarly enjoins people to look after the weak and vulnerable or else expect condemnation on the day of judgment. It asks: "Have you seen him who denies the Day of Judgement? That is he who repulses the orphan harshly and urges not on the feeding of the poor" (Qu'ran 107: 1–3).

The idea of social responsibility has taken practical form in different ways at different times. For example, Thomas Chalmers, a local clergyman, established a welfare scheme in the 1820s in the East End of Glasgow, Scotland. He withdrew his parish (local community) from statutory poor law measures and instead, instigated a system of support delivered for, and by, other community members. He believed that by removing external (state) aid, community members would take responsibility for themselves and each other. Chalmers's scheme was a source of inspiration to the Charity Organisation Society that emerged at the end of the nineteenth century in the UK and the US (Fraser, 2009). It was also demonstrated in the UK Prime Minister, David Cameron's vision of a 'big society':

> We want to give citizens, communities and local government the power and information they need to come together, solve the problems they face and build the Britain they want. We want society – the families, networks, neighbourhoods and communities that form the fabric of so much of our everyday lives – to be bigger and stronger than ever before. Only when people and communities are given more power and take more responsibility can we achieve fairness and opportunity for all.
>
> 2010: 1

This is, of course, the only one way of thinking about social responsibility. The so-called 'postwar consensus' in the UK after the end of the Second World War illustrated a very different conceptualization. According to this, it was generally accepted that social responsibility could be relegated to the state; a new understanding promised that living standards could be improved for all through the state taking responsibility for key aspects of social life including housing, unemployment, and health. Social services meanwhile would provide a 'safety net' for those unable to take advantage of the mainstream services. There was an expansion of statutory social work provision from 1945 onward and the strengthening of social work as a profession. At the same time, voluntary agencies came to be seen as an 'add-on,' dependent on statutory agencies to pay for the services they provided (Cree, 1995; Parry and Parry, 1979). The UK today has a mixed economy of care; social responsibility is shared among the state, the voluntary sector, private providers, and individuals and families working alongside one another. There is no shared view about this (if there ever was one), and instead, arguments for and against the provision of social responsibility bubble underneath the surface all the time, erupting at key moments such as parliamentary elections and at times of social unrest and economic recession.

Other parts of the developed world such as Scandinavia have chosen a very different path toward social responsibility. Here, members of society have been willing to pay higher taxes so that there is a more generous provision of social services for all. This development has not, however, been welcomed unreservedly by all. For example, Wolfe (1989a,b) argues that a consequence of Scandinavian welfare states' high levels of responsibility for others is that individuals no longer accept personal responsibility for others; their understanding of moral responsibility, he asserts, has diminished. This viewpoint shows again the contentiousness of ideas of social responsibility, as well as the crossover with notions of moral responsibility, to be discussed more fully below.

Collective Responsibility

The idea of collective responsibility is very close to that of social responsibility, but in this case, responsibility is envisaged as held by the whole, not just by a particular social group within society. From this perspective, it might be said that a government or local authority or private sector agency is responsible, for example, for a collective failure to protect and care adequately for vulnerable people. Social workers working in a particular agency may hold individual, moral, and professional responsibility for such a failure in practice (see Ife, 2012).

Collective responsibility is not just limited to organizational responsibility, however. Writing about 'green' social work, Dominelli (2012) draws attention to social work's commitment as a profession that claims to intervene to enhance people's well-being. The international definition of social work also highlights this:

> The social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilising theories of human behaviour and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work.
>
> Adopted by the IFSW General Meeting in Montréal, Canada, July 2000, IFSW 2013

In spite of this broad claim to action, Dominelli points out that social workers have played little more than a low-key role in environmental issues that increasingly impact on people's well-being, both locally and globally, although social workers across the world continue to play a key role in the aftermath of environmental disasters, whether caused by climate change, industrial accidents, or human conflict. Shaw similarly asserts that social work must wake up to its collective responsibilities. She suggests that by failing to engage with ecological issues, our current social policies are "at best not sustainable, and at worst dangerous for our continued social well-being" (2011: 1). Social workers, she advises, have an important role to play because of social work's understanding of the interrelationship between people and the environment, and social workers' ability to integrate environmental issues into their social work practice, and advocate for vulnerable populations. This leads us readily into a discussion of moral responsibility.

Horizontal Strands

Moral Responsibility

All types of responsibility have a moral dimension. Taking this further, moral responsibility should be understood to be the responsibility that underpins all others. Moral and ethical obligations make us responsible for ourselves, for others, for society, and for the planet.

Unsurprisingly, we find discussion of moral responsibility going back centuries. In the Bible, in Genesis 4: 1–16, after killing his brother Abel, Cain angrily asks God, "Am I my brother's keeper?" (The story of Cain and Abel is also found in Islamic tradition in the Qu'ran.) Cain's question has come to signify people's reluctance to accept responsibility for the welfare of their fellow human beings, that is, their 'brothers,' in the broader meaning of the term. As already highlighted, scholars such as Wolfe have argued that modern liberal democracies, such as the US and Scandinavia, have 'broken with traditional sources of morality,' relying instead on 'economic and political frameworks to define their obligations to one another.' Wolfe calls for a sense of community to be reinvigorated and with it, "a sense of obligation to the larger society" (1989b: 374). Bauman is similarly critical of what he sees as a 'modernist' approach to ethics, in which individual responsibility is exchanged for legislation, rules, and codes of behavior. He turns to the work of the philosopher Levinas (1985), who argues that ethics must begin with 'the Other,' with the knowledge that we can never fully understand or explain another person. Picking up this idea, Bauman asserts that moral relationship comes before 'being.' He writes, "I am a moral person because I recognize that dependence and accept the responsibility that follows …. My brother's dependence is what makes me an ethical being" (2000: 5). The first step, he argues in an earlier book, is to "take responsibility for one's responsibility" (1993: 185).

This draws us into literature on care ethics, and the work of Joan Tronto. Building on the insights of Gilligan (1982), Tronto points out that care is a practice, not a set of rules and principles; "It involves both particular acts of caring and a 'general habit of mind' to care that should inform all aspects of a practitioner's life" (1994: 127). Taking the example of the concept of protection, Tronto points out that the whole idea of protection demonstrates a very specific approach to human relationships; it assumes 'bad intentions,' in comparison with the idea of caring, which involves "taking the concerns and needs of the other as the basis for action" (1994: 104). Tronto observes that 'care-giving' is not necessarily the same as 'taking care of' someone. An individual or service may fulfill the first obligation but not the second. She identifies four ethical elements in care: attentiveness, responsibility, competence, and responsiveness, where responsibility is understood as responsibility to act and responsibility to take care. Tronto notes that parents are responsible for the care of their children, but responsibility may go far beyond this, as exemplified in the behavior of some Europeans during the Second World War when they tried to rescue Jews and others from Nazis. Tronto reminds us that assumptions of responsibility may be culturally and socially specific, impacted by gender, class, and family status. She proposes that we adopt a flexible approach to responsibility, rather than one that is rule bound and fixed for all time.

Professional Responsibility

Professional responsibility, along with legal and statutory responsibility, may be viewed as the other side of the coin to moral responsibility. While moral responsibility begins with a series of questions and is open to negotiation, professional responsibility tends to be presented as a set of answers. It is suggested that if practitioners meet their professional/legal/statutory obligations under legislation, practice guidelines, and given codes of practice, they will be able to sleep easy in their beds, sure in the knowledge that they have met their professional responsibilities to those with whom they are working.

Ethical codes of practice were first introduced by social work's newly formed regulatory bodies (the Northern Ireland and Scottish Social Services Council (SSSC) in Scotland and what was then the General Social Care Council (GSCC) in England and Wales) in the UK in 2002. Other countries have similar codes, as do the International Association of Schools of Social Work and the International Federation of Social Work, which jointly produced and agreed an ethical code in 2004 (see http://ifsw.org/policies/statement-of-ethical-principles/).

The 2002 UK codes of practice encompassed two sets of rules and regulations: one for social service employers, the other for social service workers. The Code of Practice for Social Service Employers set out the responsibilities of employers in the regulation of social service workers; significantly, this code of practice has not been retained by the body that replaced the General Social Care Council (GSCC) in England, that is, the Health and Care Professions Council (see http://www.hpc-uk.org). The Employers' Code in Scotland is still in place. It states that "employers are responsible for making sure that they meet the standards set out in Codes of Practice, provide high quality services and promote public trust and confidence in social services. To meet their responsibilities in relation to regulating the social service workforce, social service employers must:

- make sure people are suitable to enter the workforce and understand their roles and responsibilities
- have written policies and procedures in place to enable social service workers to meet the Scottish Social Services Council (SSSC) Code of Practice for Social Service Workers
- provide training and development opportunities to enable social service workers to strengthen and develop their skills and knowledge
- put in place and implement written processes and procedures to deal with dangerous, discriminatory, or exploitative behaviour and practice
- promote the SSSC's Code of Practice to social service workers, service users, and carers and co-operate with SSSC's proceedings" (see http://www.sssc.uk.com/Codes-of-Practice/sssc-codes-of-practice-for-social-service-workers-and-employers.html).

The Code of Practice for Social Service Workers describes the standards of professional conduct and practice required of social workers themselves. It forms part of the wider package of legislation, practice standards, and employers' policies and procedures that social service workers must meet. Social service

workers are held to be "responsible for making sure that their conduct does not fall below the standards set out and that no action or omission on their part harms the well-being of service users. Social service workers must:

- protect the rights and promote the interests of service users and carers
- strive to establish and maintain the trust and confidence of service users and carers
- promote the independence of service users while protecting them as far as possible from danger or harm
- respect the rights of service users while seeking to ensure that their behaviour does not harm themselves or other people
- uphold public trust and confidence in social services
- be accountable for the quality of their work and take responsibility for maintaining and improving their knowledge and skills" (see http://www.sssc.uk.com/Codes-of-Practice/sssc-codes-of-practice-for-social-service-workers-and-employers.html).

Parallel to the regulatory bodies' codes of practice, British Association of Social Workers has published its own *Code of Ethics for Social Work*, revised in 2012. This firstly affirms social work's "respect for the inherent worth and dignity of all people as expressed in the United Nations Universal Declaration of Human Rights (1948) and other related UN declarations on rights and the conventions derived from those declarations." It goes on to state that "social workers have a responsibility to promote social justice, in relation to society generally, and in relation to the people with whom they work," as well as "a responsibility to respect and uphold the values and principles of the profession and act in a reliable, honest and trustworthy manner." The fourth injuncture suggests that "social workers have a responsibility to apply the professional values and principles set out above to their practice. They should act with integrity and treat people with compassion, empathy and care." Two principles for ethical practice are of particular relevance to a discussion of professional responsibility: (14) "Taking responsibility for their own practice and continuing professional development," and (16) "Taking responsibility for the professional development of others."

There is nothing in any of the codes of practice with which we might wish to disagree. For the most part, the codes reflect current ideas of good practice, and represent a fairly broad consensus about what social work is and might be. The codes perform a useful function, in that they set down minimal expectations and obligations about the care individuals may expect to receive from agencies and social workers themselves. The question remains, however, about how useful these really are in the messy, 'real world' of practice; in what Schön (1983) has called the 'swampy lowlands' of professional practice, where competing ideas of responsibility may clash, and where a social worker may have to determine their own path, while coping at the same time with inadequate information and contradictory evidence. The reality is that ethical dilemmas remain, however clearly defined policies and procedures are. It is because of this that Bauman and Tronto's demand for the primacy of moral responsibility comes to the fore.

Conclusion and Implications for the Future

This article has explored a range of interpretations of the concept of responsibility. It has acknowledged that, while remaining a fundamental idea at the heart of social work, it is nevertheless a contested term, and one that benefits from reflection and analysis. Through this process, we can see that individualistic, narrowly defined, rights-based notions of responsibility may work against the very principles on which the profession of social work claims to be based. If practitioners were to truly embrace ideas of human rights and social justice, then this will only be through engagement with the reality that "I am my brother's keeper." Social workers have responsibility, as individuals, family members, members of society, professionals and, ultimately, as human beings, to act; and that must be done.

Responsibility: Philosophical Aspects

Marina AL Oshana, University of California, Davis, CA, USA

Abstract

Three analyses of the judgment that a person is a morally responsible agent are discussed. One is the reactive-attitudes analysis, whereby a person is responsible when the person is liable to a response on the part of others marked by attitudes such as gratitude and resentment. A second analysis focuses on the phenomenon of holding an agent answerable for his or her actions. The third analysis holds that judgments of responsibility are essentially statements of attribution, which focus on the ethical appraisal of conduct that can be imputed to an individual as the author or adopter of ends.

The Concept of Responsibility

The focus of this article is moral responsibility. Although the article begins with an examination of the concepts of causal responsibility and of responsibility as duty, the discussion in these sections is intended to orient the reader to the distinctive character of the concept of moral responsibility and to related philosophical ideas about what is meant when moral responsibility is ascribed to a human agent for some act or state of affairs. Attributing responsibility to an agent as to a cause is logically and conceptually distinct from claiming that the person is morally responsible for an event. Equally, discerning those tasks that a person has a responsibility or a duty to perform is different from claiming that the person bears moral responsibility for the performance of those tasks. In short, the *concept* of responsibility has a number of distinct applications, the analyses of which point to the variety of *conceptions* of responsibility.

Causal Responsibility

One interested in action theory may investigate causal responsibility. Thus, in claiming "Alice is responsible for spilling the coffee on the floor," we may be saying that Alice spilled the coffee as a result of some action on her part. In a causal context, responsibility ascriptions credit an entity with a role in bringing about an event or state of affairs, and nothing more. Assigning causal responsibility consists in identifying a salient factor that must actually operate in order for an event to transpire, and not in evaluating the moral quality of an event with which the causal factor is instrumentally associated.

Moral responsibility, and responsible agency, cannot be identified with causal responsibility. This is true for at least three reasons. First, that someone or something is causally responsible for some event or state of affairs is not a sufficient basis for moral evaluation. That the agent is causally responsible for Φ (or for Φing) is not, in and of itself, a reason to judge that the agent is good or bad, or praiseworthy or blameworthy, for having brought about Φ. It is not enough, that is, to assess the quality of the agent's will. But judgments of moral responsibility are typically of this sort.

Second, a person need not be causally responsible for the choices, acts, and states of affair for which he or she is held morally responsible – causal responsibility is not necessary for moral responsibility. For example, parents are vicariously responsible, legally and perhaps morally, for at least some of the acts for which their nonadult children bear direct causal responsibility.

Third, causal responsibility can be ascribed to events, objects, nonhuman animals, and irrational or underdeveloped humans, as well as to fully mature, rational persons. That someone or something is causally responsible for some event or state of affairs is not sufficient for the cause to be an *agent* who can be held morally responsible. An agent is a being who deliberates, reflects, decides, intends, and makes states of affair come about. An agent (ideally) establishes standards of behavior for himself and is in control of himself, unlike a patient, or a being that is acted upon, managed, or caused to assume various states. Only *qua* agent is a person in a position to realize his goals by his own effort. Even less does an attribution of causal responsibility single out a class of things that might properly be described as *moral agents*, or *members of a moral community*. When we hold a person such as Alice morally responsible for something, it is in light of certain expectations we have of Alice, given a maturity we assume of her, given what we have reason to believe she knew herself to be doing, and given the circumstances that led her to act. But the conditions for responsible agency met by Alice, and considered more fully below, are not met by very young children, animals, trees, or inanimate phenomena. Thus, while we might assert that faulty construction is to blame for the collapse of a building, what we mean is that a salient cause of the collapse was poor construction. We might allege that the baby was causally responsible for the broken lamp. But neither the baby nor the faulty construction is morally responsible for the states they cause because neither are moral agents.

Duty and Obligation

In describing a person as 'responsible' for some act or state of affairs, we may be expressing the belief that the person is bound by duty to ensure the occurrence of the act. Here, the judgment 'X is responsible for Y' is intended as a statement to the effect that X has certain responsibilities to others: tasks or obligations pertaining to Y, usually in light of X's social or role-given position. Claiming that a person is responsible for Y in this sense is to credit responsibility *prospectively*; it is to look forward to what the person is duty-bound or obligated to do. This idea of having responsibilities is analogous to Kurt Baier's notion of

'task-responsibility,' or the 'forward-looking aspect' of agent-responsibility (Baier, 1972). In its forward-looking sense, agent-responsibility consists in being socially entrusted, on customary, legal, or moral grounds, with a specified event, state of affairs, or duty. Thus, parents are responsible for overseeing the well-being of their children, adult wage earners are responsible for paying taxes, attorneys and psychiatrists are responsible for respecting the confidentiality of their clients, and so forth. In this forward-looking sense, the claim that Alice is responsible for giving Bernie the medicine would mean, at a minimum, that Alice has a duty to give Bernie medicine.

Assertions of responsibility are thus ambiguous between (1) the sense in which they attribute a prospective duty, (2) the sense in which they attribute mere causal responsibility, and (3) the sense in which they attribute moral responsibility, and perhaps imply praise or blame. In the last sense, to be morally responsible is not a matter of having or owing an obligation to another. A person may be morally responsible for those things she had a moral obligation to do, such as caring for her children. But the things for which a person can be held morally responsible in the sense of being praiseworthy or blameworthy are not restricted to things the person had an obligation or a responsibility to do. I might be held (morally) responsible for my slovenly habits, or for my acts of bravery, where neither of these attend the discharging of an obligation. Equally, the fact that an act is one I am obliged to perform does not decide whether I am morally blameworthy or praiseworthy for performing it or for failing to do so. I may have a duty as a parent to seek legal representation for my criminally errant daughter, but am I necessarily blameworthy – is it to my discredit – if I refuse to do so?

Having excluded causal responsibility and responsibility in the sense of duty as the types of responsibility with which an analysis of moral responsibility is concerned, we can turn to the latter idea. What we are interested in are the ideas of being responsible and, more specifically, of being morally responsible.

Being a Responsible Agent and Being Held Responsible

The Conditions for Responsible Agency

An account of moral responsibility must make sense of moral approval or disapproval, and it must be restricted to the activity of agents. Even if the act for which we deem a person responsible is morally neutral – that is, the act is neither praiseworthy nor blameworthy – we appraise the moral quality of the person who acts, and not simply the state of affairs he initiates. Generally speaking, when philosophers describe someone as a morally responsible agent, they mean that the person is someone whom we recognize as bearing characteristics of the sort that makes him a member of the moral community. The person is someone with whom morally significant relationships are possible, and he is a suitable subject of moral appraisal. Philosophers have offered different theories about the conditions for membership in the moral community. In Sections Holding Responsible and Being Responsible, Responsibility as Susceptibility to Reactive Attitudes, Responsibility as Attribution, and Responsibility as Accountability, three standard accounts of the characteristics that morally responsible agents must possess will be discussed. But these accounts are united by points of commonality. Notably, most philosophers agree that membership typically requires that an individual satisfy certain *epistemic* conditions and certain social and psychological conditions of *control*.

The epistemic conditions assure us that the responsible agent is self-aware, that he is means – end rational, and that he is not ignorant of the circumstances in which he acts. In addition, membership requires that the actor is acquainted with and is able to act within established moral guidelines, and that he is responsive to reasons to adjust or amend his behavior in light of these guidelines. In order to be held responsible, the moral agent must know that doing a particular act (or an act of a given type) or cultivating a particular trait of character (say, jealousy, rage, or bigotry) is right or wrong. The moral agent may be held responsible if, suffering from none of the conditions that exempt a person from responsible agency, he should have known the nature of the act or trait, and could have been motivated by the relevant moral guidelines. One's ignorance in this case might be called culpable. By contrast, one should not be held responsible if one did not know, and should not be expected to know, that the act is of an undesirable moral quality.

The control conditions ensure that the agent acts freely. The morally responsible agent is not hostage to debilitating and overwhelming neuroses of a sort that incapacitate his resolve; that is, he can govern the manifestations of neuroses by medical means or by strength of will. A person who is prone to neurosis of a certain type or scope, or who finds himself the victim of coercion or manipulation, may be a responsible agent but one whom we excuse from responsibility for specific acts when it is plain that on a particular occasion coercive or manipulative elements played a decisive role in action. Satisfaction of the control conditions for responsible agency ensure that the agent, rather than a mechanism foreign to him, actually guides or executes the agent's actions and those traits of character for which the agent is morally responsible. A mechanism of action is foreign to a person when it is one to which the person does not assent as a force by which he wishes to be moved. Although the responsible person may lack the power to alter the mechanism that leads him to act – to do otherwise than he in fact does – he is moved by his own lights. At a minimum, the morally responsible agent is capable of deliberate, intentional behavior.

Absent some of the epistemic and control conditions, a person will be a less probable candidate for responsible agency and for membership in the community of moral agents. The satisfaction of some set of these will mean that the entity is capable of responsible agency. There is obviously a threshold that decides when a person is a responsible agent, but it is not within the scope of this discussion to explore the specifics of the threshold. Let it suffice to say that the responsible agent is someone who acts knowingly and freely, and the actions and characteristics for which he is responsible are 'his own.' The account of responsibility laid out here follows closely the account defended by John Martin Fischer. One who is responsible must meet conditions for free agency. These conditions are met when the mechanism that leads the agent to act is moderately reasons-receptive and weakly reasons-responsive.

Fischer's is a 'semicompatibilist account' of responsibility, in that the question of compatibility of moral responsibility and causal determinism can be separated from questions of compatibility of causal determinism and freedom to do otherwise (see Fischer and Ravizza, 1998).

Holding Responsible and Being Responsible

While there is a fair degree of unanimity regarding the basic conditions of epistemic competence and control expected of morally responsible beings, disagreement has transpired over the proper analysis of the judgment that a person is morally responsible for his character, choices, actions, and omissions. In part, the disagreement points to the need to separate questions of what it is to *be* responsible from questions of what it means to *hold* a person responsible. Let us begin with the question of what it means to judge that a person is responsible. Three analyses, in particular, bear mention.

Responsibility as Susceptibility to Reactive Attitudes

One possibility is that in claiming that a person is responsible, we might simply be signaling that an actor, having met certain conditions for responsible agency and having displayed in his conduct a distinctively interpersonal quality of will, is a suitable candidate for a particular quality of regard and treatment forthcoming on the part of others and, perhaps, self-reflexive regard as well. This approach has been coined the reactive-attitudes analysis of responsibility ascriptions. The idea is that when we say a person is responsible, we mean that the person is rightly liable, through his behavior, to a range of responses on the part of others marked by attitudes such as gratitude and resentment, and that the person is an appropriate object of such attitudes in light of certain conditions for agency that he has met. On this analysis, the claim 'X is responsible for Y' (or 'for Y-ing') will amount to the conjunction of the claims "X possesses the epistemic and control abilities of a responsible agent," "X did (or is, or caused to come about) Y," and "X is rightly subject to the favorable or unfavorable responses of others as a result." The reactive-attitudes analysis focuses on the emotional dynamics at stake where decisions about responsibility transpire. That a person is appropriately subject to certain attitudes and practices indicates our prior assessment of the person as a free, competent agent, and offers further reason to assess the person as good or bad, praiseworthy or blameworthy.

Responsibility as Attribution

A second possibility is that judging a person responsible for some act, omission, state of affairs, or trait of character essentially is a judgment of attribution. What we are doing is appraising actions and choices that express attitudes and dispositional states attributed to the person as his own. Gary Watson labels this the *aretaic* face of responsibility for its focus on ethical appraisal of conduct that can be imputed to an individual as its agent and thus as the author or adopter of ends. Because these ends are self-adopted, acting upon them discloses the quality and character of the agent's life. Likewise, Angela Smith argues that the judgment 'P is responsible for Φ' amounts to the claim that 'Φ can be attributed to P as a basis for moral appraisal.' Smith follows T.M. Scanlon in suggesting that attributability implies answerability for those attitudes that are expressions of the actor's character and will. To simplify, to be attributable-responsible is to have judgments made about our moral character given our attitudes and actions, where the latter are connected to our underlying evaluative judgments, that is, to reasons we treat as justifications for what we did. (See Smith, 2007, 2008.)

The attributability approach does far more than assign causal responsibility, since its focus is on the intentional behavior of a human agent, his character, and his ends. At the same time, a judgment of attributability may fail to provide as much as we require of an account of responsibility. To attribute responsibility is to indicate some type of motivationally efficacious relation between the agent and his actions and attitudes, and while this relation tends to shed light upon the normative character of the agent, attribution need not involve the registration of emotions such as resentment or gratitude. Nor need it be true that an explanation of the act in question is anticipated of the actor, although, as we have seen, attributability may well be accompanied by an expectation of answerability.

Responsibility as Accountability

A third possibility is that, in judging a person responsible, we may be saying that we hold the person accountable for his behavior. Construing judgments about moral responsibility as judgments about accountability is appropriate for a number of reasons. One reason is that holding persons responsible is part of a social practice of ascribing responsibility, first by making clear any moral expectations we have of persons vis-à-vis behavior and character, and then by having in place certain social instruments that ensure adequate redress where necessary. Making moral expectations clear presumes the existence of a shared set of beliefs and a system of norms against which actions and traits of character are assessed.

This notion of accountability is variously understood. With Scanlon, David Shoemaker describes accountability as an enhanced species of *answerability*. Answerability for Φ turns on the fact that Φ must be connected to the actor's evaluative judgments, those that express reasons the actor takes to justify his actions. Thus, answerability targets the deliberative, reason-tracking aspect of the agent (Shoemaker, 2011: 616). To be *accountable*, Shoemaker argues, signals the further and distinct idea that the actor is open to sanction and susceptible to being called to account publically for his behavior because the actor has flouted a relationship-defining demand, or because a claim to goodwill has been overlooked. Gary Watson refers to the aspect of responsibility that pertains to accountability as the second of responsibility's two faces, the *culpability* face. For Watson, to be accountable-responsible is to be culpably open to blame. We judge P culpable or open to legitimate criticism because P's choices and actions reveal attitudes that express an inadequate level of regard for others, given P's relations to others (see Watson, 1996).

Others (myself included) construe accountability differently. Rather than incorporate assumptions about the responses of morally affected others into an assessment of

accountability, judgments of accountability emphasize the dimension of answerability, understood as interlocutionary competence. The focus is on the actor and the audience far less than on a judge. To be accountable signals nothing more than the fact that it is appropriate that the actor offer an explanation of his intentions or beliefs about his behavior. To be morally responsible just is to be accountable, and to be accountable just is to be answerable. It is to be positioned, in virtue of one's normative capacities in conjunction with the conditions under which one acts, to give an account of one's intentions and beliefs about one's behavior. The accountable agent must be attentive to the presence of reasons for action that others would accept are on offer and must be capable of managing her behavior in light of these. Given this narrower construction of accountability analysis, to be blameworthy would call for the further fact that one has acted in a way that reveals an inadequate level of regard for others and signals impairment of relations with others.

Note that even on the more expansive construction of accountability, blameworthiness need not involve readiness to respond with reactive attitudes. Blameworthiness and praiseworthiness call for awareness of reasons that are operative and that are standardly regarded by others as reasons to act or to refrain from acting. Oddly, perhaps, blameworthiness might not necessitate an appreciation of the distinctively moral dimensions of one's conduct (see Greenspan, 2003; Oshana 2004; Scanlon, 2008; Talbert, 2008).

Case Studies

Extreme Evil

Two varieties of cases illustrate the differences among these three analyses. First, consider examples of extreme and, some would contend, irremediable evil. If we consider the behavior of someone such as Hitler, it may well appear that he is morally 'beyond the pale' so that none of the standard reactive attitudes is an appropriate response to his 'Final Solution.' Hitler and likeminded persons are ostensibly incapacitated for ordinary adult interpersonal relationships. Such persons simply will not be responsive to the demands of membership in our moral community. At the same time, the heinous acts they have committed are properly attributed to them as perpetrators. The attributability account allows for Hitler, and similarly sociopathic or psychopathic persons, to be deemed responsible for their immoral behavior, yet permits the hesitation some might have in regarding such actors as moral interlocutors, as the accountability approach demands, or as appropriate objects of any of the ordinary moral attitudes, as the reactive-attitudes analysis would require.

Private Moral Failures

One merit of the attributability approach is that it enables us to credit persons with responsibility for matters that are essentially private, matters that are the affair of none but the actor herself. It seems unreasonable to reply to my slovenly garb, or foolish financial practice, with resentment or indignation, just as it seems unreasonable to expect that I account for these practices if they affect no one but myself. Where these practices reveal something about ends I have chosen for myself, they speak to my character – they express, as Watson claims, my own evaluative commitments and my identity as an agent. Thus, on the attributability account, they can be attributed to me as practices I bear responsibility for.

Responsibility and Free Will

Causal Determinism and Moral Responsibility

An adequate discussion of the central problems faced by any account of moral responsibility will include the problem that causal determinism poses to the idea that we have freedom of will. In brief, the problem is that, if our present choices and conduct are causally determined by past events and states, then it appears not the case that we have any freedom with respect to the performance or occurrence of our present choices and conduct. The past is something over which we have no control. And it is equally true that we have no control over the laws of nature operative in the world. Together, these claims suggest that we have no control over the present.

It is a matter of lively debate among philosophers whether or not the truth, or the likelihood, of causal determinism would affect our status as responsible agents. Some philosophers argue for the incompatibility of determinism and responsibility; if either obtains, the other does not. We cannot be both determined and responsible for our conduct. Others argue that the conditions for responsible agency are independent of determinism. On this view, the truth or plausibility of determinism aside, we can control our conduct in a manner sufficient for responsible agency. At the very least, to deny responsibility of persons whom we regard as participants in our moral framework would be to strain the limits of our natural practices. It is undeniable that persons treat one another as agents, as individuals answerable for their conduct, and the alternative – that persons cultivate an attitude of detachment from the conduct of their human associates merely because of the truth of determinism – would signal an impoverished state of human interaction that few, if any, could bear.

Retirement and Encore Adulthood: The New Later Life Course

Phyllis Moen and Jack Lam, University of Minnesota, Minneapolis, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Retirement became an institutionalized, primarily male, later life-course transition by the middle of the twentieth century; an expected, routine exit from a lifetime of paid work that was also seen as the passage to old age. However, large-scale social forces (globalization, aging populations, women's labor force participation, reduced social protections) have upended conventional expectations about retirement and the later life course. The period roughly between ages 55 and 75 years has arguably become a new life course stage, an 'encore' to conventional adulthood occurring typically after the career- and family-building years, but prior to the infirmities associated with old age.

Introduction

Both the later life course and the singular transition in it – retirement – are increasingly destandardized, risky, and ambiguous, given the large-scale social forces of globalization, aging populations (low fertility, medical advances, and extended life expectancy), and scale-backs in social protections, along with women's employment and the rise of dual-earner couples. We argue that the early twenty-first century is witnessing the emergence of a new life stage, encore adulthood, fueled by these social and economic transformations, and especially the increase in healthy life expectancy that is delaying the infirmities associated with old age. Life in this later life-course stage has become a 'project' to be figured out; even retirement is no longer a taken-for-granted routine. Moreover, apart from the Scandinavian countries, in much of Europe and North America, this is the first generation where large numbers of women have jobs they are retiring from, and large numbers of dual-earner couples are facing two retirements, 'his' and 'hers,' requiring an examination of how this experience differs for men and women, as well as whether couples plan and make decisions about retirement together. This is increasingly an unsettled and uncharted period of the life course, suggesting that past research on retirement and other experiences may well be out of date.

A Brief Historical Overview of Retirement

The life course as role trajectories (such as employment patterns) and transitions (such as retirement) is socially constructed, a product of policies and practices in education, employment, retirement, and social welfare regimes (see Kohli, 2007; Mortimer and Shanahan, 2003; *see* Motivation: Life Course and Sociological Perspectives). This highlights the shared understandings and taken-for-granted rules, roles, relationships, resources, and risks triggered at different ages and life stages, but in different ways for men and women (Moen et al., 2013; O'Rand, 2011). Age and gender are both durable predictors of life-course expectations and experiences.

The second half of the twentieth century witnessed the development of cultural norms about retirement as a typical, legitimated, and almost inevitable status passage occurring among men around age 65 years (Costa, 1998). This fostered a 'standard' education, work, and retirement (leisure) lockstep that became the institutionalized life course (Kohli, 2007), even though there were trends toward early exits (Blossfeld et al., 2011; Burkhauser et al., 1996; Ebbinghaus, 2006; Guillemard and Rein, 1993). This sequence was further legitimated by career and retirement mystiques (and the policies reinforcing them) emphasizing that success and fulfillment could be obtained only through continuous investment in occupational mobility, or at least seniority, thereby earning the full-time leisure associated with retirement (Moen and Roehling, 2005; *see* Age Policy). These career/retirement myths typically characterized the experiences, in the United States at least, of only white, middle-class, and unionized blue-collar men in the middle of the twentieth century – and not all of those. Nevertheless, the schema of continuous careers culminating in one-way, one-time retirement exits became institutionalized, accepted as both the way things are and the way things should be. As workers moved into the roles of pensioners, retirees, and seniors, they exited their status and identities as teachers, electricians, laborers, managers, technicians, doctors, nurses, or civil servants.

The early twenty-first century witnessed large numbers of women in career jobs from which they expect to retire (He et al., 2005; Purcell, 2005). Still, institutional inertia in retirement policies and practices means that social security and pension policies reward those following the continuous full-time employment assumed in the (male) career mystique (Moen and Roehling, 2005) and not the uneven employment experiences of most women, immigrants, and minorities. Moreover, now even older men in 'good' jobs are often experiencing unexpected dislocations. For example, some adults are finding themselves suddenly 'retired' as a result of layoffs or buyouts, with few reemployment prospects (Moen et al., 2010; Sweet and Moen, 2012) or else working under chronic job insecurity (Burgard et al., 2009, 2012). The risks embedded in transitional global labor markets are increasingly obvious, affecting even older workers, previously protected by their seniority (Kalleberg, 2011; Schmid, 2006; Supiot, 2001).

The first decades of the twenty-first century also witnessed a move away from retirement as an age-mandated exit (through public and organizational policies, practices, and age norms),

and away from the mid-twentieth-century trend toward progressively earlier retirement (Blekesaune and Solem, 2005; Blossfeld et al., 2011; Ebbinghaus, 2006; Gendell, 2008; Purcell, 2005). Retirement as a traditional status passage is unraveling, and retirement along with the years of encore adulthood from around 1950s to around the 1970s are becoming problematic, often requiring deliberate choices by individuals and families, a significant departure from simply following taken-for-granted scripts from full-time work to full-time leisure at a prescribed age.

In addition, there is greater heterogeneity in when and why people leave the workforce (*see* Aging and the Labor Market; Old Age Work Participation). Men and women of particular socioeconomic and racial backgrounds at particular ages at particular time periods, living in particular communities, and in particular countries are simultaneously confronting retirement-related decisions within the contexts of both their own situational biographies and a society in flux. For instance, retirement is increasingly perceived as less of a choice by workers in the USA. A study of a national sample of 1024 US adults over age 50 years found a third of retirees report they did not feel like they had a choice over the decision. This was more common among younger respondents (under 65 years); over half (54%) report they had no choice but to retire. In contrast, only 23% of those over 65 years report feeling retirement was forced upon them (Benz et al., 2013).

An Institutional Gendered Life-Course Approach

A life-course approach is useful for studying changes in retirement and the later life course in that it situates individuals in specific life stages and historical contexts, paying particular attention to their present circumstances as a consequence of both personal decisions and institutionalized options and constraints (*see* Motivation: Life Course and Sociological Perspectives). These constrained choices operate to shape peoples' role, relationship, and resource trajectories, and transitions. Thus, the life course consists of distinctive (and unequal) patterns of socially defined, age-graded experiences over time, varying across cohorts, gender, race/ethnicity, education, family background, nativity, health conditions, and historical time period (Levy and Widmer, 2013; Moen, 2014; Mortimer and Shanahan, 2003; Shanahan and Macmillan, 2007; Willson et al., 2007; *see* Life Course and Event History Analysis).

Since gender as well as government, business, and community policies and practices are major shapers of how roles, relationships, and resources are allocated, we propose the value of an institutional gendered life-course theoretical approach to promote understanding of labor market processes and inequalities characterizing the later life course and retirement (Moen, 2013). Importantly, research is necessary to capture the ways work and retirement

Figure 1 An institutional life-course model of retirement and encore adulthood. Re, regarding. Adaptedand modified from Moen, P., 2013. Constrained choices: the shifting institutional contexts of aging and the life course. In: Waite, L., (Ed.). Panel on New Directions in Social Demography, Social Epidemiology, and the Sociology of Aging, Perspectives on the Future of the Sociology of Aging. National Research Council, Washington, DC, pp. 81–119.

experiences result in contemporary men and women in different countries and different social classes arriving at and moving through the later life course equipped with very different sets of resources, constraints, and options related to employment, retirement timing, family lives, caregiving, health, and lifestyles (see **Figure 1**).

An institutional-gendered life-course theoretical frame underscores the historical times as well as the structural and cultural dynamics in which lives unfold, the uneven rates of social and institutional change, and the complex interplay between biography and history. The early twenty-first century constitutes a transformational historical period, replete with demographic changes (in the form of population aging resulting from extended life expectancy, lower fertility, medical advances), and the aging of the large Boomer cohort (born at different times in different countries but in the USA between 1946 and 1964); economic changes (in the form of global economic turbulence, new technologies, and a global labor force); and institutional changes (dismantling the social contracts equating seniority with job security, reductions and delays in public and private pensions and income). New communication technologies and investment practices have fostered a volatile global economy, with rising employer flexibility in the ability to dismiss high-cost (including older) employees and seek low-cost labor across the globe (Kalleberg, 2011; Sweet and Meiksins, 2013). Moreover, workers' incomes in retirement are contingent on their prior career trajectories, with women and men following different pathways, given the employment breaks or shifts to part-time work that women traditionally take in order to raise children, follow their husbands' job opportunities, or care for infirm relatives, such as aging parents.

Taken together, these social forces are converging to challenge conventional, widely accepted norms and expectations regarding work, retirement, age, gender, and the later life course. Contemporary retirement and later life-course decision-making is taking place in individual lives even as established, standardized cultural scripts, and institutions are being upended.

A New Later Life-Course Stage

In Europe and North America, populations and workforces are aging, yet medical and technological advances are postponing the debilitating conditions associated with old age (*see* Age Stratification). This has paved the way for refiguring the later life course. Scholars are coming to define a new life stage seen as occurring after traditional adulthood but before traditional old age. As longevity and healthy life expectancy increase, individuals in their 50s, 60s, and early 70s are finding themselves in the middle rather than at the end of the contemporary adult course, facing the challenge of having to make up this new life phase as they move along (*see* Retirement and Encore Adulthood: The New Later Life Course).

Originally named the third age (Laslett, 1989), this new stage was depicted as a period of possibility after the first age of childhood, and the second age of adulthood, but before the fourth age of infirmity. We prefer to conceptualize this life phase as 'encore adulthood,' a time to reset priorities and sometimes start new endeavors after the years of family and career building but before the frailties of old age (Moen, 2013, 2014; Moen and Flood, 2013; see also Freedman, 2008, 2012). Retirement still occurs during this new life stage, but as a project that may involve decisions and adaptations to unexpected exigencies around timing, reentries, and possibly several exits from the labor market. The vast Boomer cohort and the World War II cohort just preceding it are moving through this encore adulthood period. But they are without blueprints, confronting uncertainty and ambiguity given shifting risks, protections, norms, and even definitions of retirement (O'Rand, 2011).

There is little existing evidence as to the choices or derailments (such as by layoffs) of contemporary older workers and retirees as they progress through the encore adult years. How do peoples' social structural location, their prior trajectories and transitions, and their self-definitions of being retired (or not) shape their decisions and experiences in encore adulthood? What are the implications of choices (and options or barriers) to continue some form of ongoing public engagement in paid or unpaid work for health, life quality, and even longevity? How is this first large group of older women workers and dual-earner couples adapting to the shifting challenges of retirement?

Encore Adulthood and Retirement in the Twenty-First Century

Retirement is increasingly a phase or project enacted over a period of time, rather than a single event, as people in the encore adult years begin thinking about and planning (or else are thrust into, due to layoffs or a health emergency) life beyond their career jobs. Research is needed on the timing and voluntariness, as well as various pathways, of retirement and other encore adult transitions in various contexts. Some have greater capabilities, opportunities, and advantages in customizing encore adulthood. Education, health, and a sense of mastery or control are critical resources enabling older workers to have more choices regarding the nature and timing of retirement, such as whether to pursue bridge jobs or civic engagement as a way of continuing some form of social participation (e.g., Cahill et al., 2006; Damman et al., 2011; Kaskie et al., 2008). But sometimes older workers exit their jobs because of a push, rather than the pull of retirement (Siegrist et al., 2007; von Bonsdorff et al., 2010). In a study drawing on the 'Survey of Health, Ageing and Retirement in Europe' (SHARE), in 10 European countries, Siegrist et al. (2007) find that poor quality of work (such as low control and effort-reward imbalance) is associated with intended early retirement. Another 11-year study of Finnish municipal employees by von Bonsdorff et al. (2010) found adverse work environments and poor health in midlife predicts subsequent early retirement intentions. Also a study of 1229 Dutch male older (50 plus) workers showed midlife health problems predict early retirement intentions and actual exits (Damman et al., 2011).

However, more broadly disparities in opportunities for public engagement are a result of: (1) the cumulation of

advantages or disadvantages that are associated with class, gender, race/ethnicity, nativity, nationality, and other social markers (Willson et al., 2007); (2) global, economic, and technological forces upending job and retirement security; and (3) the aging of the population, which has raised issues about traditional safety nets (such as Social Security and health care). Some find themselves 'retired' through forced buyouts and layoffs, even as age discrimination prevents their reemployment (Roscigno et al., 2007; Sweet and Meiksins, 2013; Sweet et al., 2007). A 2012 study of a sample of 1502 US adults aged 45–74 years who were working full time or part time, self-employed, or looking for work, finds that almost two-thirds (64%) reported having seen or experienced age discrimination at the workplace. Additionally, one in five (19%) reported that they were not hired for a job they applied for, over one in 10 (12%) reported they were passed up for a promotion, and almost one in 10 (9%) reported being laid off or fired because of age (AARP, 2013a).

Others find they cannot afford to leave their (often demanding) full-time career jobs owing to financial reasons. A US study finds that 4 in 10 retirees over age 50 have problems with debt, while 10% describe their debt as a major problem (AARP, 2013b). This could become an increasingly important issue for the next cohort, given changes to pension schemes and savings patterns. A study of a national sample of 1000 Gen X'ers (born between 1965 and1976) in the USA finds that only a third are on track or have already reached their retirement savings goal, while 7% have not started saving, and another 11% do not have any retirement savings goals (Metlife, 2013).

There is evidence of a lack of well-defined roles for older workers and those who have already exited their career jobs (Casner-Lotto, 2007; Hutchens and Papps, 2005), even though human resource executives anticipate an eventual labor shortage (Ernst and Young, 2006; Leibold and Voelpel, 2006). There is also evidence of greater family engagement and expectations, especially for women, in the form of caring for older parents, spouses, adult children, and grandchildren (Chesley and Moen, 2006; Meyer, 2014; Shahly et al., 2013). Yet, remarkably little attention has been paid to the convergence of dislocational social forces reshaping the experience of those in encore adulthood, approximately 20–25 years between the life stages of building families and careers and the frailties of old age. What is known is that retirement, as we know it, is in disarray.

In the face of an aging population, current public policy goals in the USA and in Europe only seek to delay the transition from full-time work to full-time leisure by several years (in the USA, until age 70 years), or else to encourage phased retirement with work-hour reductions, often on the career job (Delsen and Reday-Mulvey, 1996; Esping-Andersen et al., 2002; Munnell and Sass, 2008; Quinn, 1999; Ruhm, 1996; Taylor, 2002). In other words, they are retaining the standard lockstep life course, only shifting the timing of transitions; few policymakers are considering innovations making ongoing or postretirement employment more meaningful and attractive or facilitating unpaid civic engagement (Freedman, 2008; Kaskie et al., 2008; McNamara and Williamson, 2013; Esping-Andersen, 2009).

The exclusion of older people from ongoing engagement is woven into the fabric of both labor markets and welfare states (see Esping-Andersen, 2009). Moreover, there are increasingly different institutional logics (taken-for-granted beliefs, values, and expectations) – some overlapping, some conflicting – within society regarding retirement and the later life course (Moen, 2013).

Research suggests that many in the encore adult years want something different than continuing their existing (often demanding) career jobs or else moving into total (nonwork) retirement. Moen and Flood (2013) find that significant numbers of Americans in their 50s, 60s, and early 70s are pursuing alternatives to the standard life course, often working in different ways – part-time, self-employed, pursuing second or third careers with new employers and/or in different occupations, and/or formally volunteering for community organizations. However, such forms of social inclusion are available for those who are in a more advantageous position in terms of education and health.

Social inclusion or exclusion of older adults may well have important consequences for health and health behaviors. There is evidence that older workers report both more smoking and more leisure-time physical activity than same-age nonworkers (Fleming et al., 2007), and that older women who leave the workforce are more likely to gain weight than those still employed (Forman-Hoffman et al., 2008). Involuntary job loss among older workers has been found to reduce physical functioning and mental health, whereas reemployment has positive health impacts (Bender, 2012; Gallo et al., 2000, 2006). One study (Bender, 2012) using the 2010 Health and Retirement Study following older Americans reports that respondents who were 'forced' to retire had significantly lower well-being.

Directions for Future Research

This is an exciting time to study retirement and the changing later life course, what we call the encore adult years, occurring prior to the infirmities traditionally associated with old age. Research is needed on the different pathways and possibilities for encore adulthood and retirement for those in different cultural and policy contexts and with different material, social, and personal resources. Are there identifiable patterns of retirement exit based on the economic and policy climates of particular nations and regions and what accounts for these different patterns (see Kinsella and Phillips, 2005; Slack and Jensen, 2008)? What pathways and transition patterns appear to be most conducive to health and subjective, as well as financial, well-being? How important is anticipatory socialization, in the form of both formal and informal retirement discussions and plans (Curl and Ingram, 2013)? Clearly this is a fertile and important area for future research.

Abstract

Whether theoretical or empirical, studies considering the links between retirement and health need to be precise about the meaning of both terms. Retirement experiences are now diverse and may have positive or negative effects on various different domains of health. Strong empirical correlations have been established in many settings but the findings of more robust causal analyses seeking to test the effect of retirement on future health are weaker and somewhat mixed. Recent and upcoming policy reform, coupled with ongoing interdisciplinary data collection and harmonization activities, mean that the potential for future research in this area is great.

Introduction

Retirement has become an increasingly important phenomenon in the life course, whether measured in terms of the proportion of life spent in retirement or in terms of the salience of retirement in people's plans and experiences. Within the context of research, the term 'retirement' is now being used to refer to many different events and processes. When defined on the basis of paid work it may refer to total exit from the labor market (e.g., a "definitive withdrawal from all labour market activity with the intention of staying out permanently," Lazear, 1987) or alternatively to ending one's main career (e.g., "the exit from an organisational path or career of considerable duration, taken by individuals after middle age, and taken with the intention of reduced psychological commitment to work thereafter," Feldman, 1994). But nonemployment-based definitions of retirement are also frequently used. Some relate to the receipt of, or eligibility for, disability or pension benefits. Others simply consider self-reported subjective economic status.

The empirical relationship between these various conceptualizations of retirement has become increasingly complex in recent cohorts of older adults. Research has documented considerable heterogeneity of individual retirement trajectories (e.g., Hans and Moen, 1999), and current and future cohorts of retirees look very different to those retiring in the mid- to late twentieth century who were more likely to have many or all these events occurring simultaneously. Further distinctions, such as whether retirement is viewed as a single life event or a gradual process, or whether retirement is viewed as voluntary or involuntary, are also perhaps more important now than they have been in the past.

Research that seeks to understand the effects of 'retirement' on 'health' needs to be just as clear about what type of retirement is being considered as it is about what type of health outcomes are the object of study. This is for two reasons. First, it is important to be clear about both concepts when thinking about the potential theoretical mechanisms and processes that might link retirement and health. Second, empirical research that seeks causal estimation of the effect of retirement on health has to address the potential endogeneity of the retirement decision, which can only be done with a theoretical discussion of the determinants of retirement set in the context of the nature of the variation available in the data. The nature of this endogeneity, and its empirical implications, will be very different for different conceptualizations of retirement. The same argument would relate to health for those attempting to understand the causal effects of health on retirement.

Theoretical Mechanisms

Leaving aside issues of causality for the time being, a large number of studies have suggested an association between retirement (variously conceptualized) and health, whether defined as physical health, cognitive function, or mental health and well-being. There are a number of processes and mechanisms that could lead to such an association, some of which are reviewed below.

If retirement is conceptualized as an exit from paid work, an understanding of the health implications of such a transition can be informed by consideration of the health risks and protections associated with work as well as the link between income (socioeconomic status) and health. Such effects will clearly differ across individuals according to the nature of the health risks in their jobs and also according to the degree to which preretirement earnings are replaced by pensions and other benefits postretirement. Furthermore, paid work fulfills important psychosocial needs in societies where employment is the norm and is central to individual identity, social roles, and social status, suggesting a withdrawal from paid work may impact negatively on mental health and well-being.

Financial considerations are also important for other reasons since they simultaneously drive the relationship between health and retirement in the other direction. Health status affects retirement both directly, through reduced productivity and wage options (e.g., French, 2005), and indirectly through financial incentives created by health insurance, entitlement to disability, and other related benefits (e.g., French and Jones, 2011). In addition, pension wealth and incentives

 http://dx.doi.org/10.1016/B978-0-08-097086-8.14045-0

have been shown to be a key driver of retirement behavior (e.g., Gruber and Wise, 1999, 2004; French, 2005), and are likely to be correlated with health through unobserved factors that drive both life cycle savings choices and health behaviors across the life course. Extensive literature exist on these effects and are summarized elsewhere (see Lindeboom, 2012 for a recent example) rather than discussed further in what follows.

Selective retirement from work (whether related to health or otherwise) can also be linked to the disengagement theory of aging. Proponents of the disengagement theory view old age as a period during which elderly individuals gradually recede from active involvement in community life that may include retirement from employment (Moody, 2010). Such disengagement is seen as a 'natural' aging process, resulting from declining physical and physiological functioning, when people voluntarily relinquish social responsibilities and expectations in order to engage more fully in personally rewarding leisure activities. Although the loss of social roles can have a negative impact on a person's well-being, this is often counterbalanced by the loss of stressors and responsibilities associated with social roles. Such a framework may be particularly applicable when thinking about retirement from one's primary career or occupation independently of retirement from the labor market entirely.

Furthermore, disengagement enables people to pursue rewarding activities, potentially increasing their well-being as a result. In this sense the process of disengagement leads to a loss of stressful roles, and an increase in well-being activities may lead to positive health benefits for retired people. Drentea (2002), for example, associates retirement with reduced stress and anxiety dependent on the ability to carry out pleasurable activities thereafter. Potential well-being enhancing activities in retirement might include greater opportunities for leisure and physical activity, voluntary activities, cognitively stimulating and learning activities, and having more time for health promotion activities such as health checkups.

Related to this, activity theories suggest that remaining active and engaged in social roles is key to successful aging and positive health and well-being outcomes. Within the context of retirement, this may include the replacement of the work role with other roles that enable the achievement of self-worth, that provide opportunities for social interaction, and that can be an outlet for creative expression. The replacement of lost roles and activities with new ones is necessary in order to maintain a healthy self-concept and a high degree of life satisfaction. Similarly, continuity theory suggests that elderly individuals might try to maintain as much of their earlier identities, activities, and style of life as they can (Moody, 2010). Both theories argue that lower levels of activity in old age are more often the result of health problems and disability than they are the outcome of a process of disengagement. Proponents of both continuity and activity theories focus on the benefits of continued social role involvement for older people as opposed to any specific job or labor market role.

While the above theoretical mechanisms and processes all provide an important way of conceptualizing potential health effects, it seems clear that some potential for heterogeneity should be acknowledged. Certain mechanisms and motivations will be more important for some individuals than for others, whether this is a systematic difference across groups such as gender and class, for example, or within-group heterogeneity. Additionally, the degree to which work, or retirement, provides the type of health benefits or risks suggested in the above theories will vary according to individual circumstances and choices. In reality there are jobs that are protective for health and others that cluster occupational risk factors for ill-health. Similarly there are economic and social circumstances in retirement that are good and bad for health. And there may plausibly be differences in role-related factors that depend on the timing of the retirement relative to the public pension or retirement age. Hence it may be important to examine subjective or benefit-related definitions of retirement as well as those pertaining to specific jobs or labor market activity. At the individual level, therefore, the effects of retirement on health will ultimately depend on which type of job and which type of retirement are relevant for the individual in question.

Empirical Evidence

Given the complexity of the possible theoretical links between retirement and health, particularly when coupled with the possibility of extensive individual heterogeneity in the effects, it is no surprise that, despite an extensive empirical literature on the subject, there is no clear consensus as to the overall effects of retirement on health. This vast majority of the literature documents significant associations between retirement (variously defined) and different aspects of physical health, mental health, and cognitive function. The subset of this literature that provides convincing empirical evidence for the existence of causal relationship from retirement to either good or bad health is much smaller. We begin by summarizing the key associations found in the relevant dimensions described above, and conclude with a briefer discussion of the degree to which these associations are found to be robust when examined in more causal frameworks.

A key review on the evidence on the health effects of work (Waddell and Burton, 2006) concluded that paid employment is necessary for obtaining adequate economic resources and income, which are essential for a person's well-being and health. It is important here, however, to distinguish between overall lifetime levels of employment, labor market participation, or economic resources and levels at any particular age or, more specifically, in older ages.

Waddell and Burton (2006) also highlighted that there is little evidence that continuing paid work at older ages is harmful for health. This view contradicts perceptions of older workers being at increased occupational risk due to declines in their cognitive and physical capacities. Indeed, for those in work, older workers are generally less likely to have accidents than their younger counterparts (Whysall and Ellwood, 2006). While the rate of workplace injury is higher among younger workers, workplace accidents involving older workers tend to result in injuries that are more serious. In terms of absence due to sickness, younger workers tend to be absent more often, but for shorter periods of time, whereas older workers are more likely to be off work for a whole week or more when they are sick (Benjamin and Wilson, 2005).

Westerlund et al. (2010) find an improvement in levels of physical and mental fatigue following retirement, especially among those who were previously working with the burden of long-standing illness. Similarly, Coursolle et al. (2010) finds retirement is associated with a reduction in depression when it is from previously stressful employment, and Mein et al. (2003) find the same association among those who retire from high quality and well-paid employment, suggesting links with both relief from work stressors and ability to enjoy retirement financially. 'Early retirement' from the workforce is commonly shown to be associated with poorer mental health outcomes (Buxton et al., 2005) and levels of self-reported health (Van Solinge, 2007), although in some instances the strength of the association diminishes as normal retirement age is approached (Jokela et al., 2010; Butterworth et al., 2006; Melzer et al., 2004). Retirement is also commonly associated with a decline in cognitive function scores when compared to later-life employment (Adam et al., 2007; Roberts et al. 2011).

Studies of physical activity among older people suggest that they encounter significant barriers to physical activity and that the period of retirement does not necessarily liberate them to become more active. Indeed, there is some evidence that retirement results in a reduction in physical activity from work-related transportation that is not compensated for by an increase in sports participation or an increase in nonsports leisure-time physical activity (Slingerland et al., 2007).

Finally, and relating to potential changes in social networks and social relationships, a study by Szinovacz and Davey (2004) finds men who retire before their partners see an increase in depression, while those with partners who have retired previously and with whom they enjoy shared activities see a reduction.

Most studies of retirement and health have focused on men, presumably because of historically stronger links to the labor market. While women are still more likely to exit the labor force at a younger age compared to men, this is changing in more recent cohorts and particularly so in the countries where female pension and retirement are rising to equal those for men. Where outcomes have been compared by gender, associations between retirement and well-being are often stronger among men with significant detrimental effects of retirement on depression and anxiety among men but not women (Butterworth et al., 2006; Melzer et al., 2004; Szinovacz and Davey, 2004; Kim and Moen, 2002). Much more research on gender differences will need to be done in future as more and more women retirees are observed with work histories covering the full life course.

Empirical studies identifying causal effects have typically tried to exploit the differences between involuntary and voluntary retirees or else used variation in pension or disability benefit eligibility ages or incentives, either across people or over time, in order to control for the endogeneity of retirement decisions. Each method has its strengths and weaknesses and these need to be argued on a case-by-case basis depending on the particular definitions of retirement and health that are being considered. Nevertheless, broad findings are that the strong associations and correlations between retirement and health are far less evident.

With regard to physical health and mortality, the results are particularly mixed. While Tsai et al. (2005) found an association between post-65 mortality rates at early retirement, Hernaes et al. (2013) find no causal effect between retirement and mortality when using pension reforms as an instrument for retirement in Norway. Jokela et al. (2010) find no association between retirement and better physical functioning for involuntary retirements while others find that retirement has a detrimental effect on risk of specific illness such as cardiovascular disease and cancer (Moon et al., 2012; Behncke, 2012), and self-reported health (Behnke, 2012).

Studies seeking to use subjective assessments of general health, either on their own or in comparison to more objective measures, typically identify additional problems in causal analysis due to potential reporting biases and effects (see for example, Bound et al., 2010). Newman (2007) shows differing effects of retirement on subjective and objective health measures in an instrumental variables framework, and while Coe and Zamarro (2011) exploit cross-EU variation in pension ages to show that early retirement may be good for health although, they also show that such effects are only temporary in the case of self-assessed health.

Effects of retirement on broader mental health and cognitive outcomes may be part of the mechanism by which subjective health assessments respond differently to retirement than do more objective measures. Mandal and Roe (2008) for example, find normal age retirement to cause improvements in depression and Charles (2004) finds positive effects on well-being and life satisfaction, as do Calvo et al. (2013). Early involuntary retirement leads to a greater decrease in purchasing of antidepressant medication when compared to normal retirement (Laaksonen et al., 2012; Oksanen et al., 2011), and a study examining the cognitive function of involuntary early retirees also reports poorer outcomes than those who continue to work (Rohwedder and Willis, 2010).

Once more, however, different approaches to the identification of causal effects can lead to differing conclusions, even for the same population over the same period of time. Using variation in pension eligibility ages as an instrument for retirement age, Bonsang et al. (2012) provide evidence of a negative effect of retirement on cognitive functioning. Coe et al. (2012), however, find that there is no evidence of a causal effect when using individual level pension fund early retirement options (sometimes called pension 'windows') as the instrument for retirement outcomes.

Conclusions

The relationship between retirement and health is complex both from a theoretical and an empirical perspective. Effects may be multidimensional and almost certainly differ across individuals. The increasing heterogeneity in retirement trajectories for recent cohorts means that taking into account such complexities has become an important issue. Clarity is needed over the precise timing and nature of the events being studied, whether in relation to retirement or to health, and also over the specific mechanisms by which they may be related. While existing empirical literature has yet to establish any conclusive or systematic causal links from retirement to health, there are certain types of circumstances and situations where effects have been found to exist, and others where their existence can be rejected.

The prospects for future work in this area are particularly good. Recent years have seen increased discourse between the various disciplines engaged in the modeling of health and retirement, and the theoretical models and mechanisms studied by empirical researchers are considerably more interdisciplinary than in the past. More importantly, perhaps, the recent advent of large-scale public-use longitudinal studies covering all aspects of socioeconomic, health, and psychosocial circumstances over long periods of time both before and after retirement age (such as the US Health and Retirement Survey, the English Longitudinal Study of Ageing or the Survey of Health Ageing and Retirement in Europe) means that empirical researchers have an unprecedented evidence base with which to carry out future investigations. The fact that these data sets collect data using comparable measurements and definitions means that international differences in economic, social, and health-care environments can be exploited in order to identify causal relationships as opposed to more simple empirical associations (see, for example, Banks and Smith, 2012).

Abstract

This article summarizes theory and evidence regarding the economics of retirement, a field that has experienced a surge of new research during the past two decades, due in part to the availability of new longitudinal data. Topics reviewed include the definition of retirement, retirement trends and patterns, and economic factors affecting retirement, including public and private pensions, wealth and savings, health and health insurance, and labor demand. The findings on these topics will be of use to policy makers around the world as they confront the opportunities and challenges posed by an aging population.

Retirement is often thought of as life's third act, coming after one's childhood and work life. Yet retirement is actually a fairly modern concept – in 1880, more than three-quarters of U.S. men, aged 65 and older, were in the labor force (Costa, 1998), meaning that many men worked until death. Since that time, rising incomes and the introduction of public and private pensions have made it possible for people to leave the labor force at younger ages. Increasing longevity and better health at older ages have also allowed people to spend more years in retirement and to receive more enjoyment from this phase of life.

As retirement has become a more significant phase of life, so too has it become the focus of more economic research. Over the past 20 years, more than 2000 articles on the economics of retirement have been published in academic journals indexed by *EconLit*. Much of the recent U.S. research makes use of the Health and Retirement Study (HRS), a longitudinal panel study of individuals over the age of 50 that began in 1992 and is designed to explore changes in labor force participation and health in late middle age and beyond. The success of the HRS has encouraged the creation of similar surveys in other countries, including the Survey of Health, Ageing and Retirement in Europe (SHARE) as well as aging studies in England, Ireland, Israel, Mexico, Japan, Korea, China, and India. With this rich data at their disposal, researchers are more active than ever in exploring issues in the economics of aging, including the economics of retirement.

Defining Retirement

While retirement may seem like a straightforward concept, it is surprisingly difficult to define. Perhaps the simplest option is to define retirement as occurring when an individual stops working for pay. This definition works well when a worker with a full-time career job that he or she has held for many years leaves this job and never works again. However, a majority of U.S. workers with career jobs retire gradually, in stages, often working for a period of time at a bridge job that offers a part-time schedule, more flexibility, or fewer responsibilities (Cahill et al., 2006). While these individuals are considered workers under the standard retirement definition, they may have more in common with fully retired individuals than they do with full-time workers.

Alternatively, retirement could be defined as occurring when an individual leaves his or her career job. But not all workers have career jobs, and it is not clear how to classify workers who switch to part-time status at their same job. A third option is to allow individuals themselves to define whether or not they are retired. This sidesteps some issues, but raises the concern that individuals with the same level of labor force participation could be classified differently. A final option is to focus on the initial claim of public or private pension benefits. While obviously an important milestone, benefit receipt need not be related to work, since individuals may be able to claim pension benefits while they are still working or to delay benefit receipt after they have stopped working.

In the end, most analysts define retirement as withdrawal from the labor force, as this is conceptually straightforward and easy to implement using most survey data. Analysts also tend to treat retirement as an absorbing state and ignore the possibility of labor force reentry, though Maestas (2010) shows that a sizeable share of U.S. workers does return to the labor force after retirement.

Retirement Trends and Patterns

The period since World War II has been characterized by a dramatic decline in the labor force participation of older men in the U.S. Data from the U.S. Bureau of Labor Statistics shows that the share of men aged 55–64 in the labor force fell from 90% in 1948 to 66% in the mid-1990s, indicating that men were retiring earlier. Since then, labor force participation in this age group has risen slowly but steadily to its current value of 70%. For older women in the U.S., labor force participation has risen continuously over the past 60 years, from 24% in 1948 to 59% in 2014. The societal trend of greater labor force participation by women of all ages appears to have swamped any movement toward earlier retirement for women.

A second notable aspect of retirement behavior is the pattern of retirement by age. Coile and Levine (2010) use data from the Current Population Survey to calculate the retirement hazard, or probability that a worker still in the labor force at a given age will exit the labor force that year, for U.S. workers.

When workers are in their mid-50s, the retirement hazard is about 5%. This rises slowly with age then doubles at age 62, the age at which Social Security benefits are first available. The hazard rate drops somewhat at ages 63 and 64 then spikes again at age 65. This is the age of eligibility for Medicare, a government health insurance program for the elderly, and was until recently also the normal retirement age for Social Security.

Though perhaps less well known, there are distinct differences in retirement rates by education, also documented by Coile and Levine (2010). While the retirement hazard by age follows the same pattern for all education groups, the retirement rate at every age is higher for less educated workers. Averaging across ages 55–69, the annual retirement rate in 2007, just prior to the recent recession, was 5% for college graduates, 7% for high-school graduates, and 9% for high-school dropouts, indicating earlier retirement by the less educated.

Retirement behavior in other developed countries displays many of the same patterns seen in the U.S. Gruber and Wise (1999) tabulate data for nine European countries as well as the U.S., Canada, and Japan. They document a decline in men's labor force participation in Europe during the postwar period that was similar to, if not steeper than, that in the U.S. By 1995, only 20–30% of men aged 60–64 were still in the labor force in Belgium, France, Italy, and the Netherlands, as compared with 50 to 60% in the U.S., UK, and Sweden; labor force participation was highest in Japan, at 75%. The retirement hazard by age in other countries is also similar to that in the U.S. but exhibits even larger spikes at the early and normal ages for public pension plans, with as many as 60–80% of remaining workers retiring when they reach these critical ages, as opposed to about 20% in the U.S.

Modeling Retirement Behavior

The economist envisions that a rational individual approaches the retirement decision by comparing the utility he or she would receive by working this year to the utility received by retiring. In such a model, wages will matter, as will potential sources of retirement income, such as public and private pensions. Economists generally believe that leisure time is a desirable good, so there will be additional utility associated with being retired (or, to put it differently, disutility from work), which may depend on the individual's health and age.

In addition, it may be appropriate to think of retirement in a household rather than an individual context, as the value of being retired may be greater if one's spouse is also retired. Naturally retirement will depend on all of the household's resources, not just pension benefits, and it may be appropriate to recognize the possibility that wealth and retirement are determined simultaneously, with a household saving more if its members wish to retire early, for example. If health insurance markets are imperfect and employment is a key means of obtaining insurance, this may also affect retirement decisions. Finally, separate from an individual's potential desire to continue working, the demand for labor from employers may affect an individual's ability to do so.

It should be evident from the preceding discussion that it will be very difficult to construct a single model of retirement that incorporates all of the factors that are potentially important and deals with each in its full complexity. Instead, researchers have tended to focus on one key piece at a time, such as public pensions, and model its effect carefully. Some researchers favor a structural approach, where the researcher posits a specific form for the individual or household utility function and uses data to estimate the parameters that define, for example, how patient the individual is when considering tradeoffs between present and future income. One advantage of this method is that the estimated parameters can be used to simulate the effect of policies outside the scope of real world experience, such as how retirement behavior would change if public pensions were eliminated. Other researchers favor making use of natural experiments – policy changes or other real-world events that have exposed groups of individuals to different conditions, such as different early and normal retirement ages in the pension plan – to learn the effect of these factors on retirement. An advantage of the latter approach is that it does not rely on correctly specifying the form of the utility function and its key assumptions are transparent – generally this boils down to demonstrating that the groups facing different conditions are either identical or can be treated as such after employing strategies to control for any differences.

Economic Factors Affecting Retirement

Public and Private Pensions

Some vocabulary is necessary to discuss the effect of pensions on retirement. A pension plan can be either a defined benefit (DB)- or defined contribution (DC)-type plan. In a DB plan, benefits are determined by a formula – for example, final earnings times years worked times 2%, so a worker with 30 years of experience receives a benefit of 60% of final salary – though public pension plans generally use complex formulas that depend on the worker's entire earnings history. In a DC plan, it is the contribution that is specified – for example, a worker might be required to contribute 10% of wages to the plan. The benefit in a DC plan depends on contributions, asset allocation and investment returns, and asset draw-down in retirement.

A pension plan can also either be fully funded, where a worker's contributions are saved to pay his or her own benefits, or pay-as-you-go, where today's contributions pay for the benefits of today's retirees. A DC plan is always fully funded, while a DB plan may be either fully funded or pay-as-you-go. The U.S. and most developed countries have pay-as-you-go, DB public pension plans, though some countries have more recently added a DC tier. Employer-sponsored private pension plans in the U.S. and elsewhere have shifted over time from DB- to DC-type plans (Munnell, 2006).

In theory, a public pension plan may affect retirement behavior if the plan results in income or substitution effects. An income effect occurs if retirement benefits are greater or less than payroll tax contributions plus a market rate of return. If benefits are greater than taxes, the individual may retire earlier, choosing to spend some of the surplus income on leisure. A substitution effect occurs if the worker is able to increase the

total value of lifetime benefits by continuing to work; if so, the pension plan effectively augments the wage and the worker may choose to work longer as a result.

Public pension systems often feature both intercohort and intracohort redistribution that create income effects. The introduction of programs like Social Security in the U.S. as pay-as-you-go plans advantaged early beneficiaries, who did not contribute over their full working lives, at the expense of later cohorts (Leimer, 1999). Within a cohort, low earners often receive higher benefits relative to contributions than do high earners because many countries incorporate progressivity into the benefit formula. Dependent spouse and survivor benefits also create intracohort redistribution, as a married, one-earner family receives more benefits than a single worker with the same payroll tax contributions.

Even in the absence of redistribution, an income effect may occur due to forced saving. Consider two types of individuals who save little for retirement: a rational, forward-looking individual who gets little utility from retirement consumption and a myopic individual who fails to plan. For both types, the pension plan raises retirement income, leading to earlier retirement. Of course, since pension income is not available until the early retirement age and workers cannot borrow against this income, they may be unable to retire until they reach this age.

The process by which a public pension plan creates substitution effects is complex. By working one more year, the worker makes payroll tax contributions and gives up a year of benefits (once past the early retirement age). However, the extra year of work is incorporated into the benefit calculation, which may raise the benefit amount. Further, the benefit amount is often raised for delaying benefit claim beyond the early eligibility age. If that adjustment is actuarially fair, lifetime benefits are similar regardless of claiming age, but if it is more (or less) than fair, this aspect of the system rewards (or penalizes) additional work. Whether the pension plan as a whole rewards additional work depends on the net of all these factors, and may vary across individuals depending on their earnings history and other characteristics.

Though not always included in standard calculations of the return to work, a final potentially important factor is that public pension plans offer a real annuity, as beneficiaries generally receive inflation-adjusted benefits that last as long as they live. With private annuity markets plagued by adverse selection (Finklestein and Poterba, 2004), workers may not have access to annuities outside the plan and may delay retirement in order to purchase a larger annuity.

With employer-sponsored private pensions, there is no redistribution aspect, since the pension is simply part of the worker's total compensation package. But DB-type private pensions typically do contain strong incentives to work to particular ages – Stock and Wise (1990) note that many pensions provide a large bonus if the employee works to the plan's early retirement age and a substantial inducement to retire thereafter. As firms shift from DB to DC plans, private pensions may have less of an impact on retirement decisions, since DC plans do not include the same types of incentives to work to or retire at particular ages.

Economists have been very interested in estimating the effect of public pensions on retirement, in part because the retirement patterns discussed above are highly suggestive of a relationship. The postwar decline in men's labor force participation occurred over the same period that workers were becoming eligible for public pensions in the U.S. and Europe and that benefits were becoming more generous. The reversal of this labor force decline in the U.S. and other countries (Coile et al., 2014b) over the past 20 years is also consistent with a role for pensions, as many countries trimmed their programs during this period. Moreover, the large spikes in the retirement hazard at the early and normal retirement ages of public pension plans do not easily lend themselves to explanations other than the obvious one, that public pensions affect retirement. Burtless and Moffitt (1986) show that the spike in retirement at age 62 in the U.S. only emerged once age 62 became the early eligibility age for Social Security. Mastrobuoni (2009) finds that as the normal retirement age for U.S. workers was raised from 65 to 66, the retirement age for affected cohorts rose by about half as much.

Researchers have also tried to directly estimate the effect of pensions on retirement, using microdata sets to compute the return to work for individual workers and making use of policy changes or differences in earnings histories or other characteristics that create variation in pension incentives across individuals. The more recent work in this literature has recognized that it is not sufficient to look at the single-year accrual, or change in lifetime pension benefits arising from an additional year of work. In the context of employer-provided DB pensions, Stock and Wise (1990) note that by working this year, the worker is effectively retaining the option of retiring in a future year with potentially higher benefits; they develop an option value model in which the worker compares the utility of retiring today to that available at all future retirement dates. Focusing on the U.S. Social Security system, Coile and Gruber (2007) show that workers are less likely to retire when they have greater gains from continued work, as measured by the option value and by a companion peak value measure that captures the financial (as opposed to utility) gain from continued work.

International comparisons provide further evidence of the effect of public pensions on retirement. Gruber and Wise (1999) calculate the financial incentive for a typical worker in each of a dozen developed countries to continue working at ages 55–69, given the features of their country's public pension plan. They show that this measure varies markedly across countries, with large penalties on additional work in Belgium, France, Italy, and the Netherlands. This correlates strongly with labor force participation rates of older men – indeed, 80–85% of the differences in participation across countries can be explained by this measure. In subsequent work, Gruber and Wise (2004) use microdata to estimate the return to work for individual workers, and show that the option value and peak value measures are key predictors of retirement in virtually all countries in their sample.

Finally, studies that estimate structural models of retirement are also relevant. Pensions enter these models as a key source of retirement income. The model is validated based on its ability to match observed retirement behavior, and model estimates may be then used to infer the role of pensions

through simulations. Gustman and Steinmeier (1986) estimate a structural retirement model that replicates the peaks in the retirement hazard at ages 62 and 65 for U.S. workers. In Gustman and Steinmeier (2005), they predict that raising the Social Security early entitlement age to 64 would cause many people to delay retirement from age 62 to 64. By contrast, French (2005) estimates that moving the early entitlement age would have little effect on retirement, but that eliminating the earnings test (which prevents individuals from receiving benefits while working) would lead individuals to work longer.

Wealth and Savings

The retirement decision is likely to depend on all of the worker's financial resources, not only on pension benefits. Economists generally believe that leisure is a normal good, that is, a good for which demand increases as income rises, and thus expect wealthier individuals to retire earlier, ceteris paribus. One challenge in testing this hypothesis empirically is that wealth is determined by the savings decisions individuals make over time. If wealthier workers retire earlier, this might reflect the fact that these workers wanted to retire early and saved accordingly rather than a causal effect of wealth on retirement. More generally, wealthy individuals may differ from less wealthy individuals in ways that are unobservable to the researcher, creating bias in the estimate.

To surmount these challenges, the primary strategy adopted by researchers who favor a natural experiments approach is to identify unanticipated changes to wealth and test whether these wealth shocks are associated with an increased probability of retirement. Researchers have made use of several sources of wealth shocks. Imbens et al. (2001) show that large lottery gains lead to a reduction in labor supply, particularly for those near retirement age. Brown et al. (2010) find that the receipt of an inheritance increases the probability of retirement, particularly when the inheritance is unexpected and thus more likely to represent a true shock to wealth.

Another source of wealth shocks is the boom–bust cycles in the stock market over the past 20 years, which have created large, unexpected fluctuations in the value of equities. Evidence from this literature is more mixed. Focusing on the late 1990s and early 2000s, Hurd et al. (2009) find no evidence that workers in households with large stock market gains retired earlier than expected, as compared with those without such gains. Coile and Levine (2006) find no evidence that changes in the stock market drive aggregate trends in labor supply, which they attribute to the fact that few workers have large stock holdings. However, Coile and Levine (2011a) find that college-educated workers age 62 and above – who are more likely to own stocks and may be more easily persuaded to retire – do reduce retirement in response to long-term declines in the value of stocks.

On the structural side, researchers who estimate structural models of retirement have augmented their models to incorporate savings decisions as well. Rust and Phelan (1997), French (2005), and Van der Klaauw and Wolpin (2008) are examples in this vein. These authors continue to primarily use their estimates to assess the effect of public pensions on retirement, but do so in a more realistic setting where workers consider retirement and savings decisions simultaneously.

Health and Health Insurance

At the simplest level, a decline in health status is expected to increase the disutility of work and therefore increase the worker's probability of retirement. There may be other effects as well – a decline in health status may lead the worker to update his or her mortality expectations, require an increase in medical expenditures, or change how much the worker values consumption in retirement. Any of these could also affect the retirement decision.

Researchers have used several approaches to assess the effect of health on retirement. One method is to include self-reported health status or work limitations in the retirement model. Studies using this method, such as Diamond and Hausman (1984), find large effects of health on retirement. However, this method is subject to the concern that self-reported health is a subjective measure, as individuals' judgments of what constitutes poor health may vary substantially. Moreover, this measure may be influenced by retirement status if people justify being retired by reporting a health problem. A second method is to use objective measures of health, such as diagnoses of particular diseases. Studies using this method, such as Anderson and Burkhauser (1985), find smaller effects, but these measures are only imperfectly correlated with working capacity. A third method is to combine subjective and objective data. However, Bound (1991) documents that the third approach can lead to bias, and also confirms concerns about the first two methods.

A final approach is to focus on negative shocks to health. As in the wealth shocks literature, the appeal of this approach is that it exploits the arrival of unexpected new information. By focusing on changes in health, this approach avoids the concern that people who are generally in worse health may differ from those in better health in ways that are unobservable to the researcher. McClellan (1998) uses this approach and finds that workers who experience a health shock such as a heart attack or new cancer diagnosis are much more likely to retire, particularly when the shock is accompanied by a large decline in functioning.

Access to health insurance may also play a role in retirement decisions, particularly in the U.S., where most individuals rely on their employer or a family member's employer for access to insurance. Madrian et al. (1994) and Rogowski and Karoly (2000) conclude that workers are much more likely to retire when their employer offers health insurance for retirees. Gruber and Madrian (1996) find that continuation of coverage mandates that allow retirees to purchase insurance through a previous employer for a period of time after leaving the firm raise retirement rates substantially, particularly for workers close to Medicare eligibility.

On the structural side, a number of authors have explored the role of health insurance. Rust and Phelan (1997) find that Medicare plays an important role in explaining the spike in retirement at age 65. French and Jones (2011) estimate that raising the Medicare eligibility age would lead workers to work longer, though Blau and Gilleskie (2006) suggest that the effect would be relatively small.

Retirement in a Family Context

While the preceding discussion largely treats retirement as an individual decision, many workers today are part of married, dual-career couples. It seems likely that workers in such families might make retirement decisions jointly or at least that each spouse might be influenced to some extent by the other spouse's decision, for several reasons. First, individuals in a married couple have access to common financial resources. Second, individuals who are married may have similar preferences – for example, both may be patient with respect to tradeoffs between present and future income. Third, each spouse's enjoyment of his or her leisure time may depend on whether the other spouse is present. One key empirical fact motivating the literature on couples' retirement is that many spouses do retire together – Coile (2004) finds that in approximately one-third of working couples, both spouses retire within 1 year of each other.

Several authors estimate structural models of joint retirement by husbands and wives, including Hurd (1990) and Gustman and Steinmeier (2000). These authors employ different models, but all find that complementarity of leisure – the idea that leisure time is more enjoyable if one's spouse is present – is a key factor driving retirement decisions. Other studies, such as Coile (2004) and Baker (2002) test for joint decision-making more indirectly, by exploring whether public pension incentives for one spouse also affect the retirement behavior of the other spouse; both find that they do.

Labor Demand

The discussion to this point has focused on factors affecting the individual's willingness to supply labor, including public and private pension incentives, wealth, health and health insurance, and a spouse's retirement status. Yet one should not assume that all older individuals who wish to continue working will be able to do so. During the Great Recession, nearly one in six U.S. workers reported losing a job (Farber, 2011). While older workers experienced lower rates of job loss, displaced older workers also experienced longer spells of unemployment and lower reemployment rates, as compared with their younger peers. Even during more normal economic times, there will be older job losers who struggle to find new work.

The effect of labor market conditions on retirement is a relatively new branch of the retirement literature. Chan and Stevens (2001) find that older U.S. workers who experience a job loss have substantially lower employment rates and earnings relative to similar nondisplaced workers. Coile and Levine (2007) show that downturns in the U.S. labor market increase retirement transitions, particularly for workers who are eligible to claim Social Security benefits. Using industry-level variation in employment in Sweden, Hallberg (2011) similarly finds that retirement is countercyclical. Late-career job loss has implications beyond retirement – Coile and Levine (2011b) show that experiencing weak labor market conditions near the age of retirement lowers retiree income, while Sullivan and von Wachter (2009) and Coile et al. (2014a) find that job loss and recessions are associated with higher long-term mortality.

Conclusion

Around the world, many countries are experiencing dramatic population aging as a result of rising longevity and falling fertility rates. This phenomenon has led to a surge of interest in the economics of aging, including the economics of retirement. The introduction of surveys such as the HRS in the U.S. and sister studies in numerous countries has enabled researchers to make tremendous strides in understanding retirement behavior and offers the promise of much exciting work yet to come. The next phase of research in the economics of retirement will be of great value to policy makers facing the difficult challenge of promoting the financial security of the elderly while ensuring that the public programs that support them are financially sustainable.

Retrieval

Asaf Gilboa, Baycrest, Toronto, ON, Canada; and University of Toronto, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Retrieval refers to a set of processes that support the recovery of stored memories. At its heart is the ecphoric process that involves an interaction between memory cues and memory traces, and the conversion of ecphoric information into conscious awareness. Retrieval also involves a set of preecphoric processes that support the search for appropriate memory cues and memory traces, and a set of postecphoric monitoring and control processes that evaluate the veracity and appropriateness of retrieved memories and endorse report decisions.

General Introduction

Retrieval is the process by which stored memories are recovered in response to memory cues that are either external or internally generated. The product of a successful retrieval process is an awareness of the target memory or information. The recovery of stored information is a basic component of many cognitive and behavioral activities. It is particularly central for functions that depend on semantic and episodic memory. For example, in the semantic domain retrieval is key to functions such as word finding during a conversation or the interpretation of written language; in the episodic memory domain, retrieval processes are required for accomplishments such as remembering where you placed your keys last night, or recollecting the night of your graduation.

The most straightforward construal of successful retrieval is that a *memory cue* activates or triggers the preexisting *memory representation* (*trace*, *engram*). Two factors that critically predict successful retrieval by this construal are the quality of the retrieval cue and the strength of the memory trace. However, theoretical models of retrieval processes have moved away from the idea that during retrieval memory traces or engrams are just 'triggered,' 'activated,' or 'brought to life'; instead, most theories put forward models in which memory cues and memory representations interact in complex ways that allow the construction/reconstruction of the experience of remembering. Thus, the success of the retrieval process depends on numerous factors, many of which may be independent of how well the information was encoded, the strength of the memory trace or the quality of the cue (**Figure 1**).

In what follows, I will outline some of these factors, as well as the processes that constitute retrieval. The overall framework presented below classifies retrieval into two primary kinds: (1) direct retrieval that involves an automatic, 'ballistic' process of the interaction between a memory cue and a memory representation and (2) indirect or strategic retrieval in which processes akin to problem-solving procedures are invoked in order to arrive at a solution to a memory problem. Both kinds of retrieval may involve postretrieval monitoring and verification processes that can be automatic or more effortful. These monitoring processes will be discussed together with the strategic retrieval components, as they tend to be invoked more during indirect retrieval. Finally, after describing this process-component model of retrieval, some discussion will be devoted to reconstruction as a central neurocognitive concept that is at the core of retrieval as well as other important constructive neurocognitive processes.

Two Routes Retrieval

At its core, retrieval involves an interaction between memory cues and memory traces or engrams. *Ecphory* is a useful term used to describe this interaction. It was originally coined by Richard Semon (1921[1904]) to denote a simple triggering or activation of an otherwise dormant memory trace (Semon, 1921[1904]). Tulving then reintroduced the term Ecphory to denote the process of activation of an engram by retrieval information provided by retrieval cues (Tulving, 1983a,b). In Tulving's model, a key component in the retrieval process is the association or correlation between the information provided by the memory cue and the information stored by the memory engram. Close correlation between these two sources of information may lead to the conversion of ecphoric information into awareness making it available to the rememberer.

An automatic memory retrieval process arises when a specific, proximal cue, one that is highly correlated with the engram, interacts with the information stored in memory immediately leading to the reconstruction of parts or the whole memory. Alternatively, the recovered product of cue–engram correlation can be the result of a strategic memory search, and can act as fuel for subsequent strategic retrieval processes.

Direct Retrieval

Direct or automatic retrieval occurs when a memory cue directly interacts with a memory representation leading to the recovery or reactivation of the target memory and bringing it into awareness. These retrieval processes operate effortlessly, annulling the need for preecphoric top-down, deliberate strategic retrieval processes. Direct retrieval processes are thought to be the bases of several nondeclarative or nonconscious memory phenomena such as perceptual and conceptual implicit memory. Thus, for example, it has been argued that priming occurs through automatic retrieval and represents a

Figure 1 A simplified model of some of the processes that may be invoked during different phases of retrieval. Retrieval cues may evoke ecphory directly or initiate preecphoric processes. Preecphoric processes involve tasks such as comprehension of the retrieval task itself through activation of long-term Memory (LTM) semantic nodes, monitoring of the familiarity and/or accessibility of the memory (e.g., feeling of knowing), initiation of a search process, setting up a search strategy and description of the requirements of the memory task. This is a reiterative process until ecphory occurs or until retrieval attempt is aborted. Ecphory itself involves both a correlation between the memory cue and memory trace and a conversion process making it available to consciousness. The product of the ecphoric process is subject to several postecphoric processes including automatic 'feeling of rightness' monitoring, effortful editing, and if needed updating of the cue description and search strategy. Control processes act on the product of the monitoring processes to decide whether to report, reinitiate search, or abort retrieval attempts altogether.

relatively pure form of these processes (Graf and Mandler, 1984). By this view, all explicit, or declarative, memory retrieval is 'contaminated' by more controlled, conscious, retrieval processes. However, automatic processes may also play an important role in retrieval of certain types of conscious information. That is, some aspects of declarative memory appear to require little attentional resources and are thus considered relatively automatic or bottom-up processes and are supported by different mechanisms than controlled, strategic retrieval. For example, retrieval of associative semantic information is thought to occur through *spreading activation* of network nodes that represent different aspects of the information. This spreading activation process occurs very rapidly after the presentation of the cue and that does not appear to significantly tax attentional resources (Miyashita, 2004). In episodic memory too, some retrieval process appear to be driven in a bottom-up fashion, leading to the automatic capture of attention by retrieved memory content that mediate the conscious awareness of that information (Ciaramelli et al., 2008). Direct retrieval of information depends on two primary variables: the strength of the memory representation or memory trace and the strength or efficiency of the retrieval cue, as described below.

Early models of memory emphasized the importance of the strength of memory representation as the prime determinant of the dynamics and success of retrieval processes. By this view, competition among different memory traces as well as the decay functions of the memory traces themselves were the key factors to be considered in accounts of memory retrieval. Stronger memory traces are more likely to gain access to consciousness; memory strength is determined at encoding and is influenced by the interval elapsed between the encoding phase and time of attempted retrieval. Different such models have been proposed over the years, and most of them have in common the idea that every item (whether presented or not) possesses certain strength in memory that a memory trace's potency is determined by the efficiency of encoding and the decay over time of that strength.

Significant portions of the empirical evidence from memory research can be interpreted in light of *memory trace strength account*. For example, the manner in which an item is encoded has dramatic effects on the likelihood and manner in which that item can be retrieved which supports the premise that memory encoding determines the initial representational strength. This is most eloquently argued and convincingly demonstrated by the *levels of processing framework* (Craik and Lockhart, 1972). Incidental encoding of items that involves deep (meaningful) processing such as placing them in a sentence leads to better recall of these items compared with shallow processing such as counting the number of phonemes. Similarly, when subjects use visual imagery during presentation of names of objects, later recall for the imagined items is greatly enhanced. These examples are compatible with the idea that initial strength of the memory trace influences its later retrieval. The idea that retention intervals and memory strength decay functions determine retrieval has also been supported by research. For example, patterns of decrease in retrieval success as a function of increase in retention interval may reflect a gradual decrease in memory trace strength. Moreover, fluctuations in trace strength are thought to be responsible for invoked as an explanation why memories that were inaccessible can sometimes be retrieved at a later time.

The second factor that significantly influences direct retrieval is the relevance or *quality of the retrieval cue*. Retrieval cues that are closely related to the memory trace are more effective for successful retrieval. Such close relationships are at the heart of the influential encoding specificity principle. *The encoding specificity principle* proposes that greater similarity between the conditions present at encoding and the retrieval cues available at recovery generates the most effective retrieval cues and increases the likelihood of remembering (Tulving and Osler, 1968). The correspondence between encoding and retrieval contexts ensures that the retrieval cues are encoded with the memory trace and are therefore closely related and relevant to it at retrieval. By manipulating encoding specificity, studies have produced counterintuitive results that are best explained in terms of the correspondence between encoding and retrieval environments. For example, when participants study target words (e.g., tree) paired with loosely related cues (e.g., cloud), and are later cued either with the loosely related cue or a highly related cue (e.g., pine), the loosely related words serve as better cues for retrieval. Thus, while the trace-dependent view of retrieval focuses on the strength dimension of memory, the cue-dependent view focuses on it content and its more qualitative aspects.

Both the trace-dependent and cue-dependent views of retrieval capture important aspects of retrieval and in particular of the ecphoric process; but neither view, nor the two together, tells the complete story. The state of the memory trace, regardless of how well it is described, and the quality of the retrieval cue, irrespective of how accurately characterized, are not the only factors that influence retrieval. In what follows, some of the other critical factors will be illustrated.

Indirect Retrieval

Rememberers cannot control the ecphoric operation itself, which is considered to be automatic or ballistic. However, if external or internal cues do not elicit memory directly through ecphory, control may be exerted through strategic manipulation of the production process, biasing the processing of environmental cues or generating cues internally. These 'working with memory' procedures (Moscovitch and Winocur, 2002) involve *preecphoric* strategic processes that influence the way environmental cues are processed, those that are designed to assess the likelihood of successful retrieval and those that aim to create the optimal conditions for successful retrieval. *Postechporic* processes involve different types of memory monitoring, updating search parameters if need be as well as decisions to report or abort the memory search.

Preretrieval

A directed, strategic, process of retrieval needs to be initiated with the establishment of a *retrieval mode*. A prerequisite of successful effortful retrieval is that the cognitive system is dedicated to act in the service of retrieval. Retrieval mode is a cognitive state that ensures that external or internal events are treated as retrieval cues. Consider, for example, examining an old picture of a child. Then comes along a friend and says, "You know who that is." At that moment, the picture ceases to be merely an object of perceptual examination or aesthetic satisfaction and begins to serve as a cue for memory retrieval; the cognitive orientation toward it changes. Tulving (1983b) considered retrieval mode to constitute a tonically maintained state for the duration of a retrieval task. Once in retrieval mode, a set of metacognitive evaluative processes takes place, designed to assess the likelihood a memory would be available given the cues and context. These operate even before an actual retrieval attempt is made and certainly before retrieval occurs and give rise to a 'feeling of knowing' (Hart, 1965) or knowing that you don't know. 'Feeling of Knowing' refers to the subjective experience that a particular piece of information is available in memory despite not being currently available to recall; individuals experiencing 'feeling of knowing' would think that the information would be recognized if presented or be available to recall at a later time. Several mechanisms are hypothesized to support such preretrieval metamemory processes. For example, familiarity with the cue itself or the subject matter of retrieval can determine metamemory judgments, or the accessibility of partial cue-related information from memory can be used to determine the likelihood of the target memory itself being retrieved. Moreover, these mechanisms may interact and contribute to feeling of knowing in a cascade under different conditions and at different delays (Koriat and Levy-Sadot, 2001).

Other strategic processes are used to initiate the memory search, frame the memory query, and constrain the memory survey until local associative/cue-dependent processes can produce a possible answer. Establishing an efficient *search strategy* is often key to successful retrieval. Several retrieval strategies have been described in the literature. Prominent strategies during recall are *direct retrieval*, *plausibility judgment*, *source-constrained retrieval*, and *generate-recognize*. Direct retrieval involves direct comparison of the information provided by the retrieval cue with information in memory, in search for a close match. Plausibility judgment describes inferential decisions that are based on the plausibility and general feature overlap of the retrieval cue itself with respect to general memory representations rather than a search for specific details in memory. Source-constrained retrieval describes a mental reinstatement of the encoding strategy or conditions during retrieval so that items encoded in a particular source are preferentially recognized. Finally, generate-recognize involves an initial recall of multiple candidates and then using recognition memory to determine which candidate best answers the memory problem. The choice of optimal search strategy is sensitive to features such as the delay since encoding, demands of the retrieval task (e.g., amount of detail required), personal characteristics of the rememberer (e.g., age) and so forth.

The choice of search strategy can have dramatic effects on retrieval outcome. Consider for example the study described above using weak associates at encoding (cloud-tree) where retrieval cues are either reinstated weak cues or extralist strong ones. The encoding specificity principle would predict an advantage for the reinstated cues over the extralist ones. However, when participants are given information about the associative strength of each retrieval cue and instructed to use direct retrieval for weak associates but generate-recognize for strong associates, the advantage of reinstatement is eliminated (Higham and Tam, 2005). Thus, it can be argued that the quality of the retrieval cue, as described by the

encoding specificity framework, is not an objective measure of the goodness of fit between memory cue and memory trace, but rather is influenced by the production strategies exercised. Optimizing the search strategy to the kinds of cues available changes their efficacy as retrieval cues.

One of the primary functions of selecting an appropriate search strategy is to support the preliminary process of *description or focusing*. The purpose of focusing is to create a refined retrieval description or query of the sought-for information (Burgess and Shallice, 1996; Schacter et al., 1998). For example, in focusing the retrieval query posed by the friend with respect to the old picture, one might consider whether the child in the picture is likely to be a common childhood friend, or a childhood picture of a current common acquaintance. The search process and range of possible memory answers would dramatically change based on the outcome of this initial focusing or further description of the memory problem. Generating additional internal cues as input to production is a central mechanism in the service of cue description preecphorically. Individuals tend to produce large amounts of incidental information to the main retrieval task that serve to probe memory for additional clues and specify new search contexts. For example, in attempting to determine the identity of the child in the picture, one might try to recall details about one's primary school, extracurricular activities, or summer camps. The purpose of description processes is often to provide a correspondence or alignment between the requirements of the memory task and the content of memory and specify the type of trace that would satisfy the retrieval demands.

Postretrieval

An additional set of strategic processes operates postecphorically to assess the outcome of retrieval through various monitoring and verification processes and to determine whether to report that outcome, reinitiate a search process, or abort the search altogether. Note that while cue-dependent and trace-dependent views of memory focus on quantitative aspects of memory, here the focus is on the accuracy of the memory. Accordingly, in addition to studying hits and omissions that reflect memory quantity, accuracy-oriented approaches to memory also focus on commission errors. Postretrieval monitoring and control processes help edit out retrieved memories that are likely to be wrong and also support decisions about the amount detail and specificity required and so they influence both the accuracy and quantity of the information.

Postecphoric monitoring and verification involve both automatic and controlled processes. Thomas Reid observed that intuitive conviction is a fundamental of human memory (Reid, 1969[1710–1796]). The idea that certain memories carry with them an intrinsic sense of truthfulness has been particularly influential in theories of self-related memories. Compared with other types of information, autobiographical memories carry with them an extraordinary sense of confidence in their veracity, regardless of whether this sense is justified or not (Brewer, 1986). The mechanisms underlying this kind of 'felt rightness' *automatic monitoring* are poorly understood (Moscovitch and Winocur, 2002) but there is evidence for its rapid and automatic influence over memory (Gilboa et al., 2009). Thus, 'felt rightness' refers to the ability to rapidly or intuitively appreciate the appropriateness, suitability, and accuracy of a response with relation to the goals of the memory task and/or current personal goals. It precedes any elaborate cognitive verification of the truthfulness of the memory and the context in which it is retrieved. It has been hypothesized that intuitive 'felt rightness' is the result of an early categorical selection ('true'/'false') of memory cues based on their compatibility with general cognitive schemata that guide or serve as scaffold for memory reconstruction. The intensity of the intuition is a function of the strength of the schema and the extent of compatibility or deviation of the memory from it. Strong representations endow memory traces with more intense 'felt rightness.' The reason autobiographical memories produce the strongest sense of confidence is that the most salient, rich and robust cognitive schema is that of the self.

Early, rapid, and emotionally based decisions to endorse or reject an item may be followed by a more thorough, cognitive assessment of the memory's plausibility whether, for example, the initial response is incompatible with other knowledge or memories. Retrieved memories are constantly evaluated for their veracity by comparing them with other retrieved content, available information and with the memory task or cue descriptors by processes that are akin to problem-solving procedures (Burgess and Shallice, 1996). These have been dubbed 'editor processes' and they heavily rely on working memory processes for holding in mind multiple pieces of information, and performing logical operations for deciding whether various retrieved aspects are compatible with each other and with the memory task. They also heavily rely on processes such as conflict detection and conflict resolution.

One influential memory framework that emphasizes postecphoric processes in memory retrieval is the *source-monitoring framework* (Johnson et al., 1993). When retrieving a memory, contextual information such as when and where the item was encountered is sometimes as important as recalling the item itself. Postecphoric processes play a central role in attributing the retrieved information to a particular source, placing it in the appropriate spatiotemporal context. Retrieval of the source is often a decisive factor in making the decision of whether the information retrieved is the one being sought and even whether the information is a memory rather than a thought or fantasy.

Reconstruction and Rebinding in Retrieval

The above discussions of direct retrieval and of the component process model of strategic working with memory might leave the impression that the information 'resides' in the memory trace waiting to be 'activated' by the correct key introduced by internal or external memory cues. As mentioned in the introduction, retrieval should in fact be thought of as a reconstructive process where the fidelity between the original events and the reconstructed experience is imperfect at best (Bartlett, 1920; Schacter et al., 1998). The issue of reconstructive memory is detailed elsewhere in this volume. However, in the present context it is important to mention it because many so called memory errors that reflect the reconstructive

nature of memory arise at retrieval. For example, the content of retrieval cues can bias or distort the content of the memories that are retrieved in many different ways. Some of these include the influence of expectations during retrieval on the content of memory (suggestibility), source misattributions, gap filling, and the misinformation effect (Loftus, 2005). While the reconstructive nature of retrieval has primarily been investigated by paradigms amplifying the fallibility of memory and its proneness to error, it is important to note that this characteristic of memory is crucial for some of its primary functions. Specifically, it is the reconstructive nature of memory that allows it to be used flexibly in multiple contexts and for multiple purposes including planning for possible future scenarios and imagining possible futures.

The neurobiological instantiation of memory reconstruction during retrieval is captured by ideas that describe memory in terms of binding. Binding involves linking together representations of different kinds of information that are processed by different neural substrates. These mechanisms are important over the short term as in during perception or working memory, but are also critical when fragments of information from long-term storage need to be linked together. During encoding binding mechanisms are important for understanding how different aspects of the memory trace are connected and how memory cues might be bound within the memory trace. At retrieval, they are critical for the reinstatement of patterns of activity through processes such as pattern completion as part of a cue–trace interaction. In that sense, memories are not located anywhere in particular within the brain. Instead, they are distributed across large expansions of neural substrates that represent different features of a prior experience. They involve almost all parts of the association cortex and limbic system. Critical elements of the component process model of retrieval described above may be broadly described in terms of the neural substrates that support them. The memory engram and memory cue are properties of items and contexts that are represented in a distributed fashion across relevant unimodal, transmodal, and heteromodal association cortical areas. Limbic areas, and in particular the hippocampus, are critical for binding together these disparate representations into coherent ensembles during encoding and to pattern-complete these ensembles during retrieval. Finally, structures within the prefrontal cortex and possibly posterior heteromodal cortical regions interact with these limbic-neocortical ensembles to guide, organize, and regulate the rebinding process.

Conclusion

The notion that retrieval is the result of a simple ballistic process of an interaction between a memory cue and a memory trace only describes a very limited aspect of a much more elaborate and complex process. Accordingly, describing retrieval only in terms of cue and trace characteristics is an insufficient account of it. Instead, retrieval is a complex reconstructive, reiterative process involving many neurocognitive systems. While schematic models such as the one presented here are extremely useful in formulating ideas about how such complex systems might work and interact, they are also necessarily a gross simplification and are not to be taken at face value. The implementation of each of the components described by the model is considerably more complex both at the cognitive and the neural level. Some of these components, such as ecphory and retrieval mode, are better understood than others, such as automatic monitoring or cue description. Future research in cognition and cognitive neuroscience will undoubtedly elucidate these processes or perhaps prove some of them wrong or redundant.

Abstract

Retroactive interference (RI) refers to when newly acquired information impairs the retention of previously acquired information. RI is observed in both the declarative and nondeclarative divisions of the long-term memory system. RI is observed across the life span. However, susceptibility to RI is heightened in the elderly and patients with memory impairments. RI is believed to occur via two mechanisms: (1) retrieval interference, where two or more memories sharing the same/highly similar retrieval cue compete for retrieval, and (2) consolidation interference, where new incoming information disrupts the memory strengthening of recently acquired memory traces. Consolidation RI appears to be the main contributor of RI-induced forgetting, the effects of which can be reduced if consolidation RI is delayed and/or minimized. Here we discuss representative behavioral and neuroscience research demonstrating the effects of RI.

Background

Imagine you are sat comfortably on your sofa, chatting to an old friend on the telephone when there is a knock at the door. You answer the door finding a salesman attempting to convince you to buy his products. Five minutes later, when you finally get a word in, you politely decline, returning indoors to your phone conversation … but you can no longer recall the details of your recent phone conversation, "What were you saying about your father's birthday party?" This is a fictional example of retroactive interference (RI), whereby listening to the salesman interfered with your retention of your friend's birthday story.

RI is a phenomenon that occurs when new information impairs the ability to recall previously acquired material. This is the opposite of proactive interference (PI) where previously acquired material interferes with the ability to recall new information.

Historical Overview

RI has been documented for over a century by multiple memory researchers (e.g., Bigham, 1984; Müller and Pilzecker, 1900; Skaggs, 1925; McGeoch and McDonald, 1931). However, it is Georg Elias Müller and his student Alfons Pilzecker who are considered to be the pioneers of RI research with their seminal work reported in *Experimentelle Beiträge zur Lehre vom Gedächtniss* (*Experimental Contribution to the Science of Memory, 1900*).

Müller and Pilzecker (1900) conducted a series of experiments investigating memory for learned paired associations when they incidentally discovered RI. This led Müller and Pilzecker (1900) to investigate further this phenomenon, ultimately providing quantitative evidence for RI for the first time. Müller and Pilzecker (1900) also provided the first suggestion of memory consolidation, i.e., the strengthening of new memories over time; a theory that is gaining increasing acknowledgment in the fields of neuropsychology and neuroscience. For a review of Müller and Pilzecker's (1900) research, see Dewar et al. (2007).

In the wake of Müller and Pilzecker's (1900) findings, further researchers began to acknowledge that forgetting could be induced by subsequent interference (e.g., Jenkins and Dallenbach, 1924; Skaggs, 1925). In consideration of such research, McGeoch and McDonald (1931) proposed that the then widely accepted Decay Theory of forgetting should be replaced by an Interference Theory of forgetting. In contrast to the Decay Theory, which proposes that memories are lost due to the mere passage of time, the Interference Theory proposes that forgetting occurs when memories interfere with, and disrupt, one another (Baddeley, 1999). As a result of RI research in the fields of neuropsychology and neuroscience (e.g., Briggs, 1954; Underwood and Postman, 1960; Cowan et al., 2004; Wixted, 2004, 2005, 2011; Dewar et al., 2007), the Interference Theory is now considered to be the most prominent theory of forgetting.

RI in Different Memory Systems

The currently dominant theoretical account of human memory divides memory into different systems (Tulving, 1985), one of which is long-term memory (LTM). LTM can be further subdivided into declarative (facts and knowledge) and nondeclarative (implicit and procedural) memory (Tulving, 1972); RI is observable in both subdivisions of LTM. Here, we discuss representative research that demonstrates the effects of RI within the declarative and nondeclarative human memory systems.

RI in Declarative Memory

In Tulving's (1972) taxonomy, declarative memory is subdivided into episodic and semantic memory. Episodic memory provides the ability to recall detailed information and mentally 'relive' a past episode or event from our lives. For example, if you attempt to recall a special day from your life, whether it be a wedding or birthday, it is likely that you can recall a vast quantity of detailed information from this particular episode in the form of *what* occurred during the

episode, *where* the episode took place, and *when* the episode occurred (Tulving, 1983). In contrast, semantic memory is typically responsible for the recall of factual information, deprived of contextual details. For example, you are likely to know that London is the capital of the United Kingdom but it is unlikely that you can specifically recall the contextual details of *where* and *when* you learned this fact.

In experimental neuropsychology paradigms, RI in episodic memory is typically observed when new learning is followed by further incoming information, thus generating interference and impairing the ability to recall the initially learned material (e.g., Müller and Pilzecker, 1900; Skaggs, 1925; Dewar et al., 2007). In Müller and Pilzecker's (1900) seminal research this was demonstrated by probing retention of newly learned material following one of two critical delay periods: a delay filled with further stimuli or a delay devoid of further stimuli. Retention was markedly lower following the filled delay than the unfilled delay, thus revealing a clear effect of RI.

In Müller and Pilzecker's (1900) early experiments, the same type of material (paired syllable lists) was used as the 'to-be-retained' and interpolated 'interference' material. Thus, the question was proposed that RI may be due to a material similarity effect. However, Müller and Pilzecker (1900) demonstrated this to not to be the case; RI remained even when the filled delay comprised of material (to-be-described landscape pictures) that was highly dissimilar to the initially learned material (paired syllable lists). Müller and Pilzecker (1900) concluded that RI was due to general cognitive engagement during the postlearning delay, and not due to material similarity. Using a modern adaption of Müller and Pilzecker's (1900) paradigm, Dewar et al. (2007) investigated the possible differences in the level of RI generated by different types of postlearning activities. The authors compared the effects of five distinctively different 8-min filled delay activities and an 8-min unfilled delay on the retention of wordlist material. The five filled delay activities applied were as follows: solving short mathematical problems, playing a spot the difference game, attending to an audio recording, watching 'real-world' video clips, and detecting tones. It was found that each of the different filled delays was capable of generating significant levels of RI; retention of wordlist material was lower following each of the five *filled* delay activities than following the unfilled delay. It is hypothesized that RI was observed across all filled delay activities due to additional, new incoming information during activity performance, and that when minimizing this additional, new incoming information, as in the unfilled delay, retention can be improved. In addition to new incoming information from the external environment causing RI, Craig et al. (2014) demonstrated that internal autobiographical memory activities also cause RI. Further to this, Dewar et al. (2012) demonstrated that the RI effect persists over the long term: stories learned prior to a 10-min spot the difference game were retained less well over 7 days than were stories learned prior to a 10-min unfilled delay.

In addition to material similarity not being necessary for RI to occur, the acoustic similarity of initially learned and interpolated material also appears to have little influence on RI generation (Baddeley and Dale, 1966). In contrast, the semantic similarity of initially learned and interpolated material does appear to be an important variable in the level of RI observed (Skaggs, 1925; Barnes and Underwood, 1959; Baddeley and Dale, 1966). Using an AB–AC paradigm, Barnes and Underwood (1959) demonstrated that when learned wordlists shared a high level of semantic similarity, a higher level of RI was observed than when learned AB–AC wordlists shared a low level of semantic similarity.

RI in Nondeclarative Memory

Nondeclarative memory is comprised of implicit and procedural memory. Implicit memory is memory acquired through the senses and serves to identify objects and the structure of language, often in the recognition of themes or patterns. In contrast, procedural memory allows for the learning and long-term retention of specific motor actions and responses, e.g., riding a bicycle or tying a shoelace. RI is observed in both implicit and procedural memory.

RI in Implicit Memory

The susceptibility of implicit memory to RI has been an unresolved debate for some time, with many researchers favoring the interpretation that implicit memory is immune to RI (see reviews by Anderson and Neely, 1996; Schacter and Cooper, 1993). This conclusion was based on the findings of several influential studies (e.g., Graf and Schacter, 1987; Sloman et al., 1988) that did not find evidence of RI in implicit memory. However, the results of several other investigations have demonstrated the presence of RI in implicit memory (Lustig and Hasher, 2001; Nelson et al., 1989; Winocur et al., 1996). As a result of this research, implicit memory is not considered to be immune to RI.

The effects of RI can be observed within different modalities of implicit memory. For example, RI is observable in tone pitch memory. Using a delayed-comparison task of recognition memory for pitch, Massaro (1970) investigated whether a 'blank' period (akin to the previous discussed 'unfilled delay') after the presentation of nonverbal stimuli would function to improve retention for the sensory traces in memory. Results demonstrated that the 'blank' period after tone presentation was sufficient to improve retention when the tone's duration was brief (~2 s). Thus, Massaro (1970) demonstrated that the avoidance of postlearning RI was capable of producing a benefit in the long-term retention of audible sensory information.

In addition, memory for a novel scent is also susceptible to RI (Walk and Johns, 1984; Köster et al., 2002; Olsson et al., 2009; Morrin et al., 2011), despite having previously been thought to be immune (Engen and Ross, 1973; Lawless and Engen, 1977). Walk and Johns (1984) investigated RI in scent memory by exposing participants to two food scents, followed by (or not – control condition) further potentially interfering 'unhelpful' stimuli (a third scent; the name of a third scent), or 'helpful' stimuli (the name of one of the original two scents). Participants were then presented with four scents of which one was the original scent that they were asked to try to correctly recognize. Results demonstrated a clear effect of RI: identification of the original scent was significantly higher when the original scent was followed by the control condition, than when it was followed by the further 'unhelpful' stimuli.

RI in Procedural Memory

The effects of RI in procedural memory can be observed in the learning of a novel motor skill. Acquisition of a new motor skill

can be disrupted if one attempts to acquire a further, different motor skill shortly after learning the initial skill (Robertson et al., 2004). Using a force-field task requiring dynamic transformations, i.e., the learning of new muscle forces, Brashers-Krug et al. (1996) found that when learning of one pattern of forces (force A) was followed by training on a second opposing pattern of forces (force B), recall of the initially encoded pattern (force A) was impaired after a 24-h delay. In addition, Shadmehr and Brashers-Krug (1997) demonstrated that two motor maps could be learned and retained (for at least 5 months), only if training sessions were separated by a minimum of 5 h. If this was not so, significant RI was observed in the retention of force A. Interestingly, Kremer et al. (2011) found that a similar level of RI was generated when acquisition of a new motor skill was followed by both highly similar and highly dissimilar internal practicing of a new, different motor skill, i.e., no physical movement was involved, only internal imagery. The level of RI generated by internal practicing was also highly similar to an external unrelated reading task.

RI in Different Populations

Developmental Effects

Although the majority of research concerning RI has focused on adults, evidence suggests that RI can be observed in early human development. For example, infants demonstrate RI in visual recognition tasks (Turati, 2008) and mobile reinforcement paradigms (Rossi-George and Rovee-Collier, 1999). However, the trajectory of RI susceptibility during development is less clear with research suggesting that susceptibility does not alter during development from childhood (~4 years of age) to adulthood (~18 years of age) (Howe, 1995; Lee and Bussey, 2001; Darby and Sloutsky, 2013).

Healthy Aging

From adolescence onward, susceptibility to RI increases with age (Hartman and Hasher, 1991; Shimamura and Jurica, 1994; Winocur et al., 1996; Ebert and Anderson, 2009; Solesio et al., 2009; Solesio-Jofre et al., 2011). Using an AB–AC paradigm, Ebert and Anderson (2009) compared susceptibility to RI in younger and older adults. Participants first learned a list (A–B) of 12 semantically related word pairs (e.g., knee–bone). Twenty minutes later, a second list (A–C) was learned in which the same stimulus words were paired with new response words (e.g., knee–bend). Both lists were learned to criterion. Postlearning, participants were asked to recall the first (A–B) list. Results demonstrated an increased susceptibility to RI *and* PI (interference by A–B learning during later A–C learning) in older adults than younger adults.

Patient Populations

Some patient populations are profoundly vulnerable to RI. This is particularly evident in those with memory impairment, e.g., dense focal amnesia, amnestic mild cognitive impairment (aMCI), and Alzheimer's disease (AD). A hallmark of these conditions is an acute forgetfulness for newly acquired information (anterograde amnesia) and loss of previously learned information (retrograde amnesia).

Cowan et al. (2004) investigated the effects of RI in patients with amnesia as a result of head injury. In two experiments, patients were presented with lists of words (Experiment 1) and stories (Experiment 2). These stimuli were to be recalled immediately and/or after an extended test delay (10 min in Experiment 1; 1 h in Experiment 2). Results demonstrated an especially high level of forgetting when presentation was followed by performing a series of cognitive tasks than by an unfilled delay. Interestingly, in Experiment 2, when the unfilled delay was increased to 1 h, a substantial memory improvement was observed. Patients who had previously retained an average of 7% of material after the filled delay were now able to successfully retain an average of 79%. In fact, the authors found that three of the four patients who were unable to retain any material (i.e., 0%) when learning was followed by a filled delay were now able to retain 78, 85, and 90% of learned material.

Della Sala et al. (2005) expanded on the findings of Cowan et al. (2004) by assessing RI in patients with aMCI (a prodrome of AD). In their study, Della Sala et al. (2005) presented patients with prose passages that were followed by a 1 h filled delay (comprising of various psychometric tasks) or an unfilled delay of equivalent duration. Results demonstrated a striking memory improvement when learning was followed by an unfilled delay (55%) compared to a filled delay (20% retention). Dewar et al. (2009, 2010a,b, 2012) provided further evidence for the benefit of minimizing RI in amnesic patients, including patients with mild AD. Thus it is suggested that an increased susceptibility to RI is a key cognitive mechanism underlying memory impairment in many patients with amnesia (Cowan et al., 2004; Della Sala et al., 2005; Dewar et al., 2009, 2010a,b, 2012). Further more, these findings provided an unexpected insight into the spared capacity to retain new information in amnesic patients when RI is minimized, an attribute that was previously thought not to be possible.

Mechanisms Underlying RI

Two key mechanisms have been proposed to account for RI: retrieval interference, where two or more memories that share the same/highly similar cues compete during retrieval, and consolidation interference, where the consolidation of memory traces is disrupted by new incoming information.

Retrieval Interference

Tulving and Thomson (1973) suggested that when memories are retrieved in the same/highly similar contextual settings that they were encoded in (e.g., location, auditory, and visual context), recall performance will be superior than retrieval that occurs within a highly dissimilar contextual setting (Mensink and Raajmakers, 1988; Anderson et al., 1994). This was most famously demonstrated by Godden and Baddeley (1975) who found that when deep-sea divers learned a list of words on land or under water, recall performance was superior when retrieval was performed within the same contextual setting as during learning. Contextual components of an encoding environment can act as cues, aiding the retrieval of memory

traces that were encoded in such a context. However, when different memory traces share the same or, highly similar cue, competition for retrieval can occur, potentially inhibiting the retrieval of the desired memory, i.e., retrieval interference.

Retrieval interference is typically observed in the lab using the AB–AC paradigm (Skaggs, 1925; Postman and Alper, 1946; Briggs, 1954; Wixted, 2004; Dewar et al., 2007). In the AB–AC paradigm, participants are presented a list of word pairs – e.g., cat–glass, tree–car, sky–train – i.e., the 'A–B' list. During the recall test, the first word of each pair ('A' words) is presented to cue retrieval of the paired second word ('B' words). Following a delay, a further list of word pairs is presented in which the first words remain the same as in list A–B, but the second words are replaced with new words – e.g., cat–sun, tree–shoe, sky–book – i.e., the 'A–C' list. During a subsequent A–B recall test, the presentation of the cue word, e.g., 'cat' ('A' word), can result in interference at retrieval of the associated 'B' word (glass) due to competing retrieval of the associated 'C' word (sun).

Incisa della Rocchetta and Milner (1993) found that patients with left frontal lobe removal showed increased RI during a cued recall task. The authors suggested that the integrity of the left frontal lobe is vital in strategic retrieval and for the suppression of potentially interfering items in verbal memory.

While retrieval interference can be observed reliably in the laboratory, it is still unknown whether memory traces for interpolated material are simply stronger than older traces, or whether their learning/retrieval may actually weaken old memory traces (Dewar and Della Sala, 2013).

Critically, retrieval interference cannot account for all aspects of interference-induced forgetting. For example, even when interpolated task material is highly dissimilar to the previously learned material and unlikely to have similar retrieval cues, interference can still be observed. In such cases, it is likely that an alternative mechanism of RI is responsible – consolidation interference.

Consolidation Interference

On the acquisition of new information, it is believed that new weak memory traces are formed. Over time these traces are strengthened by consolidation processes. Consolidation takes place in the background, without intentional memory rehearsal, and ultimately results in the ability to recall recently acquired information at a later point in time. Two stages of consolidation have been postulated: 'synaptic' and 'systems' consolidation (Dudai, 2004). Synaptic consolidation is believed to occur in the minutes/hours that follow new learning, boosting memory strength at the cellular level. In contrast, systems consolidation is believed to occur in the hours/years that follow new learning, involving the reorganization and storage of the new memory in the neocortex.

Despite early recognition of the notion of memory consolidation (Ribot, 1881, 1882; Burnham, 1903), or memory 'preservation' as termed by Müller and Pilzecker (1900), it has been mostly ignored within modern neuropsychology other than a few notable exceptions (e.g., Gaskell and Dumay, 2003; Bosshardt et al., 2005a,b; Wixted, 2004; Dewar et al., 2007, 2012). However, an increasing volume of behavioral research now provides considerable evidence for the existence of memory consolidation. With this comes a growing acknowledgment of 'consolidation interference.'

Wixted (2004) suggests that consolidation interference occurs due to consolidation 'resources' not being infinite. Wixted (2004) suggests that when new learning is directly followed by further information, consolidation resources are divided between the two sets of material, leading to a lower level of consolidation of the initially learned material, and thus resulting in a lower level of retention. Carefully designed experiments provide sound evidence that it is indeed consolidation that is hampered by new incoming information: since consolidation strengthens newly formed memory traces over time, a core prediction is that consolidation interference should be especially detrimental if it occurs immediately after new learning, i.e., when the newly formed memory trace has had little chance to strengthen. If, on the other hand, consolidation interference occurs following a delay, the new memory trace should have had sufficient time to be strengthened, thus being less vulnerable to subsequent interference, resulting in increased retention. Such a 'temporal gradient' is indeed observed, as demonstrated initially by Müller and Pilzecker (1900). This effect has been widely observed, spanning declarative (Müller and Pilzecker, 1900; Skaggs, 1925; Dewar et al., 2009) and nondeclarative (Brashers-Krug et al., 1996; Shadmehr and Brashers-Krug, 1997; Valeria Della-Maggiore, 2005) memory, as well as animal neuroscience (see later).

In relation to the discussed patient populations and their increased susceptibility to RI, one possible explanation for this increased susceptibility is an expansion on Wixted's (2004) suggestion that consolidation 'resources' are not infinite. Indeed, as found by Cowan et al. (2004), Della Sala et al. (2005), and Dewar et al. (2007, 2009, 2010a,b) when postlearning RI is minimized, a higher level of material can be retained in amnesic, aMCI, and early AD patients. Moreover, Dewar et al. (2009) demonstrated a temporal gradient of RI, i.e., the longer the delay between new learning and RI onset, the greater the level of newly learned material retained. This suggests that consolidation resources are indeed still available in patients (if not in the same quantity as in healthy matched controls) and some consolidation can occur when provided with optimal conditions, i.e., minimizing RI (Dewar et al., 2009, 2010a,b, 2012). It should be noted that not all patients show a benefit of minimizing RI (Cowan et al., 2004; Della Sala et al., 2005) and that some patients, e.g., those in the moderate stages of AD, show a reduced benefit (Dewar et al., 2012). In this case, it could be that consolidation resources are depleted to the point that new memories are not able to be consolidated, potentially due to marked damage to the hippocampus (Cowan et al., 2004; Della Sala et al., 2005; Dewar et al., 2012).

Sleep memory research also provides evidence for consolidation interference as a cause of RI in declarative (Buzsáki, 1998; Gottselig et al., 2004; Ellenbogen et al., 2006a,b) and nondeclarative (Diekelmann et al., 2009; Robertson et al., 2005) memory. Given that new sensory information is minimal during sleep, sleep should also provide conditions conducive to consolidation (i.e., minimal RI), thus enabling the processes to occur. Ellenbogen et al. (2006b) used the AB–AC paradigm as a means for examining sleep-related consolidation of newly acquired declarative memories. In this research, participants learned a first list of paired material (A–B) prior to a 12-h

period of sleep or wakefulness. Following the 12-h delay, participants were presented with a second list of paired material (A–C), which shared the same cue items, i.e., 'A.' The level of RI generated from A–C material during subsequent retrieval of A–B material was then used as a measure of the strength of A–B memory traces, i.e., the greater the level of consolidation, the stronger the A–B trace, and the less susceptible to A–C interference the trace should be. Ellenbogen et al. (2006b) demonstrated a significant benefit of sleep in A–B list retention. The authors suggested that consolidation processes during sleep were able to strengthen the new memory traces, increasing their immunity to subsequent RI from similar traces.

In addition, a beneficial effect of postlearning sleep can also be observed in nondeclarative memory whereby newly learned motor skills are more stable and resistant to subsequent interference if training is followed by a period of sleep (Walker et al., 2003). Further to this, postlearning sleep leads to enhanced speed and accuracy of skill performance at a delayed retesting if postlearning sleep occurs in the absence of further training during the retention period. Walker et al. (2003) suggested that the long-term retention of newly learned motor skills is highly dependent on processes that occur during sleep, ensuring memory traces are made resistant to subsequent RI.

The association between sleep and consolidation has been demonstrated to hold a great depth with both slow wave sleep and rapid eye movement sleep associated with the consolidation of declarative (Empson and Clarke, 1970; Tilley and Empson, 1978; Rasch et al., 2007; Lahl et al., 2008; Diekelmann et al., 2009) and nondeclarative memories (Diekelmann et al., 2009; Walker et al., 2003; Maquet et al., 2003), respectively. Indeed, it is still being debated whether sleep-related improvements are related to minimal interference during sleep and/or due to more active neural processes present during sleep (Ellenbogen et al., 2006a).

As a result of the discussed research, Dewar et al. (2007) proposed a novel model of forgetting in which consolidation interference is a key mediator in the generation of RI, and thus the forgetting of recently learned memories. Moreover, the authors suggested that when the immediate postlearning delay is devoid of further information, a higher level of consolidation can occur, and thus a greater level of learned material can be retained. For details see Dewar et al. (2007).

RI and Neuroscience

As in neuropsychological research, RI is readily observable in animal neuroscience. In such investigations, RI is typically induced by the administration of protein synthesis inhibitors (usually toxins or antibiotics) shortly after new learning has taken place (Davis and Squire, 1984; Dudai, 2004; Mednick et al., 2011; Wixted, 2004). These drugs are believed to disrupt the consolidation of recently acquired memory traces (Dudai, 2004). When consolidation is disrupted shortly after learning, animals retain very little of what they have just learned. However, when consolidation is disrupted after a delay, animals are able to retain substantially more of what they have just learned (Dudai, 2004). This temporal gradient of pharmacological RI is reminiscent of that seen in neuropsychological research (see earlier) and shows that consolidation interference is particularly detrimental to new, fragile memories which have not yet benefitted from initial strengthening (Izquierdo et al., 1999; Mednick et al., 2011).

In neuroscience, the key mediator of RI is believed to be the inhibition of synaptic consolidation in the highly plastic hippocampal circuit (Carr et al., 2011), which occurs prior to the much longer process of systems consolidation where memories may become hippocampus-independent (Dudai, 2004). Specifically, it appears that RI occurs during synaptic consolidation as a result of disruptions of hippocampal long-term potentiation (LTP). LTP is a long-lasting enhancement of synaptic transmission that occurs in response to brief, high-frequency stimulation of postsynaptic neurons (Wixted, 2004). It is induced during encoding of a new memory and maintained during subsequent consolidation. New LTP induction and memory encoding both interfere with the maintenance of LTP, and thus the consolidation of recent memories, if they occur shortly after new learning (Mednick et al., 2011). According to Mednick et al. (2011) new encoding interferes with the consolidation of recent memories since the induction of new LTP (associated with new encoding) inhibits the maintenance of recent LTP (associated with consolidation). This suggestion mirrors findings and hypotheses in neuropsychological research (e.g., Cowan et al., 2004; Della Sala et al., 2005; Dewar et al., 2009, 2010a,b, 2012).

In addition to LTP inhibition, the disruption of 'offline replay' is also believed to play an important role in RI. Offline replay is the sequential reactivation of hippocampal representations. For example, in rodents, hippocampal activity associated with recent activity (e.g., walking along a track) is actually replayed during subsequent periods of wakefulness. This process is highly suited to promote memory consolidation (Carr et al., 2011).

Animal model lesion studies strongly associate the hippocampus with consolidation, whereby an increased susceptibility to RI, and impaired retention, is observed when a lesion in the hippocampus is made (Jarrard, 1975; Bartko et al., 2010). It is also of note that patient populations who present with hippocampal degradation (e.g., aMCI and AD) demonstrate an increased susceptibility to RI. Thus, while RI mechanisms are not fully understood at present, it is likely that by interfering with hippocampal LTP and offline replay, synaptic consolidation interference occurs, resulting in the impaired retention of new memories.

Neuroscience research also provides evidence for the biological basis of retrieval interference. A large body of research (see, e.g., Miller and Cohen, 2001) suggests that the prefrontal cortex is involved in guiding the online dynamics of competition, thus ensuring that the correct response 'wins' and is successfully retrieved. Shimamura et al. (1995) demonstrated that patients with frontal lobe lesions exhibit increased retrieval interference susceptibility. Moreover, Johansson et al. (2007) demonstrated that sustained prefrontal event-related potentials (ERPs) were related to the level of observed retrieval interference. In contrast, Tendolkar et al. (1997) found no evidence of prefrontal activity in an ERP study investigating retrieval interference. More recently, in an animal model, Bartko et al. (2010) demonstrated an increased susceptibility to retrieval RI in rats with perirhinal and postrhinal cortical lesions.

Thus, while a strong relationship between the hippocampus and consolidation RI is observed, the biological basis of retrieval interference requires further investigation.

Summary

In summary, the neuropsychological and neuroscience research discussed in this article demonstrates the detrimental effects of RI on LTM retention in both declarative and nondeclarative memory. The detrimental effects of RI are visible across the life span, from infants to the elderly. While susceptibility to RI is stable during development, from adolescence, susceptibility increases throughout healthy aging. Further to this, many patients with memory impairment are particularly vulnerable to RI, and this vulnerability is hypothesized to underpin the memory problems observed in such patients. RI is believed to occur via two mechanisms: retrieval interference and consolidation interference. Consolidation interference appears to be the main cause of RI-induced forgetting, the effects of which can be reduced if consolidation interference is delayed and/or minimized. This benefit is believed to be due to enhanced LTP and offline replay which occur shortly after learning.

Revolution

Abstract

The term 'revolution' has evolved from a general notion of political 'turning-over' to refer more specifically to a rapid, fundamental transformation of the state and social structure, accompanied by mass uprising from below. Theories of revolution that emphasize structural conditions tend to focus on the revolutionary seizure of state power, while theories emphasizing actor motivations view revolution as an open-ended process of social transformation. This article examines the definitions and alternative explanatory frameworks, and considers the future of revolution in a changing global context.

In the 150 years since the *Communist Manifesto*, revolution has mainly occurred not in the heart of industrial capitalism, but in countries at the periphery, with significant peasant participation. Theories of revolution in the twentieth century (*see* Revolutions, Theories of; Revolutions, History of) evolved from descriptive 'natural cycles' of revolution, to explanations emphasizing social-psychological factors, to structuralist theories, adding state and international structures to Marxian class analysis of history. Fourth-generation theories re-emphasize agency, drawing on cultural studies to examine ideological frameworks and subjective motivations of actors. The end of the Cold War contributed to new interest in a broader conception of the revolutionary potential within civil society, including the mainly nonviolent 'people's power' social movements that toppled Communist Party states in Eastern Europe and dictatorship in the Philippines; the 'negotiated revolutions' in Central America that opened space for political democratization; the Zapatista call for an awakening of Mexican civil society; the 'Arab spring' uprisings of 2011; and resistance against globalization, suggesting the intriguing prospect of an emerging global civil society.

Conceptualizing 'Revolution'

The earliest studies of comparative politics noted recurring conflict between elites and populace, sometimes leading to power 'revolving' from one group of rulers to another within a society. After the French Revolution of 1789 (*see* French Revolution, The), the term 'revolution' took on new meaning as a radical overthrow of the social and political order itself (Goldstone, 1998). The nineteenth-century European challenges to monarchic authority by the rising bourgeoisie and the class conflicts of industrial capitalism, punctuated by Marx and Engels' [1848] (1998) publication of *The Communist Manifesto*, focused attention on historical processes in analyzing revolution. After Lenin and Mao adapted Marxist theory to the Russian and Chinese revolutions (*see* Russian Revolution, The; Chinese Revolutions: Twentieth Century), the decades following World War II saw a wave of national liberation movements against colonialism and neo-colonialism (*see* Third World; Colonization and Colonialism, History of; Imperialism, History of). Contrary to Marx's expectation that revolution would occur in the most industrialized capitalist countries, led by the proletariat, revolutions in the twentieth century occurred in the global periphery through mobilization of peasants and artisan workers.

The Mexican Revolution of 1910 (*see* Mexican Revolution, The) and the revolution that eventually brought the Communist Party to power in China in 1949 (*see* Chinese Revolutions: Twentieth Century) were not specifically against colonial rule, since Mexico like most of Latin America had won independence in the early 1800s and China was never fully colonized. In both of these major revolutions, the peasantry played a key role, and anti-imperialist nationalism was an important unifying ideology in mobilizing a much broader base than just the incipient industrial working class.

Common Usage

The eclectic 'socialism' of many Third World revolts and nationalist decolonization movements (*see* National Liberation Movements), and their use of unorthodox tactics of guerrilla warfare – analyzed by practitioners such as Mao Zedong, Che Guevara, and Vo Nguyen Giap – led those characteristics to be generically associated with 'revolution.' This usage was reinforced by Cold War counterinsurgency strategies aimed at forestalling radical change in national political systems, which were seen as extensions of the global East–West contest. The collapse of most colonialism after World War II (*see* Colonization and Colonialism, History of) was sometimes a revolutionary moment, in those cases where it entailed not only reformulating the state to throw off external rule but also fundamentally reordering internal social relations. The large number of newly independent states with a history of having been colonized and/or lagging in development were collectively labeled the 'Third World'; and the Cold War imposed a simplistic dichotomy in which they either remained in the Western camp (where the U.S. had replaced the European colonizers as hegemon), or underwent socialist revolutions and aligned with the Soviet Union. This framework never accurately captured the complex and varied reality of the two-thirds of the world's countries that were put into this box, but it did focus attention on the potential for radical change on the periphery of the global system. National liberation movements that posed radical challenges to the domestic social order, often long after decolonization, included notable cases such as Cuba (*see* Cuban Revolution, The) in 1959, southeast Asia (*see* Vietnamese Revolution, The) and southern Africa in the 1960s and 1970s, and Central America in the 1970s and 1980s.

The term 'revolution' moved away from this historically specific usage after the conservative religious turn in the 1979 Iranian revolution, the Eastern-Central European uprisings against Communist Party states after 1989 (*see* Revolutions of

1989–90 in Eastern Central Europe), and the end of the Cold War and other global power shifts at the dawn of the twenty-first century.

Sometimes the term 'revolution' is used loosely to refer to any kind of paradigmatic shift, as in 'the Industrial Revolution,' 'the Reagan revolution,' or 'the behaviorist revolution' in social sciences. In another variant usage, 'revolution' is contrasted with reformism to connote a radical political program, short time horizon, and willingness to use extreme (violent) means; as in Malcolm X's call for African-American liberation "by any means necessary," or J.F. Kennedy's warning that "those who make peaceful revolution impossible will make violent revolution inevitable" in Latin America.

Political Revolution and Social Revolution

The term 'political revolution' is employed to specify the application of the concept to a national political system. This usage does not include issue-specific social movements, nor all sudden changes of political power through *coup d'état* or civil war (*see* Civil Wars; Insurgency; Social Protest; Social Movements and Political Violence; Social Movements, History of: General). However, 'political revolution' can refer to a wide range of revolts, rebellions, and mobilizational seizures of power – including those led from above such as the Japanese Meiji Restoration of 1868 (*see* Meiji Revolution, The), Nasser's 1952 coup in Egypt, or the 1944–54 period in Guatemala – if they propose major lasting changes in the political order (Goldstone, 1998; DeFronzo, 2006).

Skocpol's influential work (1979: p. 4) proposed a more restrictive focus on 'social revolution':

> Social revolutions are rapid, basic transformations of a society's state and class structures, and they are accompanied and in part carried through by class-based revolts from below. Social revolutions are set apart from other sorts of conflicts and transformative processes above all by the combination of two coincidences: the coincidence of societal structural change with class upheaval, and the coincidence of political with social transformation.

By this narrower definition, social revolution is a relatively rare phenomenon.

Alternative Ways of Understanding Revolution

Goldstone (1980) usefully grouped explanations of revolution into three generations of theory, with a fourth generation emerging since the late twentieth century. In the 1920s and 1930s, a first generation of 'natural histories' of revolutions used techniques of 'thick description' and inductive logic based on empirical observation of major Western revolutions. These efforts to identify key actors, factions, sequences, and patterns helped establish the phenomenon of revolution as a distinctive subject of comparative study.

From Description to Explanation

In the 1950s and 1960s, the upheaval associated with decolonization led to a second generation of 'general theories of political violence.' Some focused on the individual psychological motivations of people experiencing frustrated expectations, as in the 'relative deprivation' approach. Frantz Fanon's *The Wretched of the Earth* (1965) interpreted political violence as redemption, healing the psychological wounds of colonization. Another branch of general theories sought explanations of political violence at the societal rather than individual level. Huntington's (1968) influential work drew on modernization theory, attributing revolutionary upheaval to economic modernization in developing countries, which raised expectations faster than they could be accommodated by the lagging development of political institutions (*see* Modernization, Sociological Theories of).

Critics of modernization theory in the late 1960s and 1970s pushed general theories of political violence in new directions. Tilly (1978) challenged the assumption that social systems were in natural equilibrium, arguing that conflict was normal, so explanations of political violence should focus on the relative resource mobilization capacity of power contenders. Moore (1966), in a sweeping macrohistorical comparative work, showed that there is no single, unilinear process of modernization. Extending Marx's class analysis to a more detailed classification of landlord–peasant relations, he combined this variable with distinct political forms of class struggle in agrarian societies undergoing commercial modernization, to map out different possible revolutionary outcomes.

Moore's (1966) work was the point of departure for Skocpol's (1979) groundbreaking study most associated with a third generation of 'structural theories' of revolution (see also her critique of Moore in Skocpol, 1994). Shifting from the actor-centered focus that characterized general theories of violence, these theories highlighted the structural relations between units that created revolutionary opportunities. They built multicausal explanations based not only on class dynamics, but also on other aspects of the structures of society, the state, and the international system. Structural theories identified revolutionary conditions in the combination of administrative breakdown of the state, dissident elite political movements, a permissive world context, and widespread rural rebellion. Some focused on the types of state structures most vulnerable to revolutionary overthrow, including politically exclusionary authoritarian regimes, neopatrimonial dictatorships, and directly ruled colonies. Goldstone (1991) examined the interaction of factors such as population growth with political institutions and social structure, developing quantitative indicators of revolutionary conditions. Structuralists defined revolution in terms of successful outcomes, distinguishing revolutionary seizure of state power from cases in which one or more necessary conditions were absent.

Structure versus Agency: Emerging Fourth-Generation Theory

An alternative to defining revolution as a set of structural conditions is to conceptualize it in terms of distinct systems of ideas and beliefs that subjectively mobilize actors. An emerging fourth generation of 'actor-centered' theories of revolution emphasize the defining role of ideology, culture, and identity of the subjects who make revolution. To borrow Mao's metaphorical observation that a single spark can ignite a prairie fire, these theorists shifted attention from the wind, temperature, and dryness of the grasslands to the spark itself. This contrasts

with Skocpol's (1979) quotation of Wendell Phillips's statement that "revolutions are not made; they come."

Fourth-generation theories inspired new debates about whether revolutions can be accurately predicted on the basis of structural conditions, particularly in light of the surprising developments in the Iranian and Eastern European revolutions of the late twentieth century. Structuralists began re-examining the role of ideology in revolutions and the interaction of states with other domestic and international structures (Skocpol, 1994). New insights from cultural studies and feminist theory challenged the more state-centered concepts of revolution (Foran et al., 2008). These new perspectives defined revolution not as an outcome achieved by overthrow of the state, but as an ongoing process of transformation of society, involving both the institutionalization of a new order and the consolidation of a new ideology, guided with different degrees of success by different styles of leadership. The emphasis on process rather than outcome seemed more fruitful in light of the ambiguous and indeterminate course of some revolutions, including the negotiated end in the late 1990s to armed conflicts in Central America.

Islamism and Other Revolutions of Values

The 1979 Islamic revolution in Iran highlighted the growing influence of Islamism, also known as political Islam, as an ideological impetus for mass mobilization around radical social and political change. The revolutionary forces arrayed against the Shah of Iran were a diverse coalition, but the religious current led by Ayatollah Ruhollah Khomeini succeeded in gaining power and imposed a theocracy based on the radical clerics' interpretation of Islamic religious law, or shariah. Elsewhere in the Middle East and beyond, a number of groups emerged or expanded that sought a guiding role for Islam in social and political life, though they varied widely in both their strategies for achieving that end and their interpretations of the religion (*see* Islam: Middle East). They ranged from reformist variants such as the Justice and Development Party in Turkey and the Muslim Brotherhood that won Egyptian elections in 2012 after the ouster of Hosni Mubarak, to radical groups such as the Taliban in Afghanistan or the Al Qaeda terrorist network responsible for the 11 September 2001 attack on the World Trade Center. While the Iranian version of Islamism supported a revolution, the Al Qaeda network took aim primarily at U.S. global power, and the Wahhabi movement supported the continuation of conservative monarchy in Saudi Arabia.

Among possible explanations for the rise of radical and sometimes revolutionary political expressions of Islam, political scientist Samuel Huntington posited that the end of the Cold War would see a 'clash of civilizations' in which culture and religious values would be the new axis of fundamental global conflict. This interpretation found support in the analysis of cross-national values surveys (Inglehart and Welzel, 2005; Welzel, 2013) that revised modernization theory to emphasize the way national cultural traditions shaped attitudes and values toward emancipation. Others saw the Islamist phenomenon as fueled by multiple factors, including a backlash against globalization and the corresponding spread of Western culture; moral outrage over corrupt and oppressive regimes in the Arab world; frustration among educated, unemployed youth; and a rejection of U.S. hegemonic pretensions in general and policies in the Middle East in particular.

Religion can be an ideological framework encouraging acquiescence to the status quo – the 'opiate of the masses,' in Marx's famous dictum – or it can provide a unifying message and values framework for potential agents of revolutionary change to mobilize against social injustice. For example, Catholicism in Latin America once served to rationalize the Spanish invasion and centuries of racial/class stratification. Then the Vatican II reforms of the 1960s opened the door for Liberation Theology, a movement advocating a 'preferential option for the poor' within Latin American Catholicism, which influenced revolutionaries in the region as well as a variety of other grassroots initiatives in the succeeding decades. By the late 1980s, the Liberation Theology influence was waning, as Pope John Paul II launched a theological counteroffensive and as more conservative evangelical Protestant religions spread in Latin America.

Another example of fundamental ideological challenge to social hierarchies came from indigenous movements in Latin America. In the poor southern Mexican state of Chiapas, the 1994 Zapatista uprising of Maya peoples rejected the economic impact of neoliberal, free-market policies on the peasantry as well as historic suppression of indigenous rights. The Zapatistas formed their own autonomous governing structures, and their discourse called for a political model of 'governing by obeying' and 'a world in which many worlds may fit.' A mass movement in Bolivia, also motivated by a critique of both global capitalism and ethnic exclusion, overthrew the government and brought the election in 2005 of Evo Morales, the first indigenous president in the country where indigenous peoples are a majority. Some of that government's policies reflected the indigenous cosmovision, including groundbreaking legislation that granted legal rights to Mother Nature. Similarly in Ecuador, the mass mobilization of indigenous people led to a new constitution recognizing the rights of nature and the ancestral communitarian principle of 'Buen Vivir' (the concept of the right to a good life).

Fourth-generation theorists of revolution highlighted what Selbin (2010) calls 'story,' the narratives that have powerful subjective appeal and can generate mass mobilization. The shift of focus from the state to the power of ideas in society, or 'cultures of revolution,' calls attention to the myths, historical figures, and symbols that stir collective memories and action (Foran et al., 2008). Venezuelan President Hugo Chávez invoked the historical figure of the anticolonial liberator Simón Bolívar, along with socialist ideology, to proclaim a 'Bolivarian revolution.' After his election in 1999, Chávez combined radical redistribution, mobilization of the poor, and anti-imperialist rhetoric. These policies represented a radical change in class relations, but they were carried out through state reforms (concentrating executive power) backed by an electoral mandate, generating sharply polarized discourses over whether Chávez should be considered a revolutionary, a populist, or a dictator.

Democratic Revolutions of the Post-Cold-War Era

Tectonic shifts in power configurations at the international level may create historic openings for revolution. The end of the Cold War, punctuated by the taking down of the Berlin Wall in 1989 and the collapse of the Soviet Union in 1991, may be one

such moment. A number of new states and new regimes emerged out of the collapse of erstwhile Communist political systems across East-Central Europe. Ironically, regimes founded on an official ideology that espoused revolution had fallen to popular uprisings. After Mikhail Gorbachev, the last General Secretary of the Communist Party of the Soviet Union, renounced the use of Soviet military force to protect other Communist regimes, the collapse came quickly and in most cases with little violence, suggesting that legitimacy had long since eroded. The Soviet collapse reverberated across other parts of the world that had once been Cold War hot spots, contributing to state collapse in Somalia and economic crisis in Cuba. At the same time, the end of an era of superpower sponsorship of authoritarian client states created a potential opening for democratization elsewhere.

Viewed in historic perspective, some saw the transitions from Communism as a continuation of what Huntington (1991) had identified as a 'third wave' of democracy that began with the mid-1970s collapse of fascism in Portugal and Spain and spread to Latin America and beyond (*see* Democratic Transitions). Notwithstanding some self-congratulatory triumphalism in the West, the fall of Communism had to do with a combination of intrepid civil society activities in Europe, a series of economic and political liberalization initiatives by Gorbachev that revealed the extent of discontent with a stagnant system, and a rapidly shifting calculus by individual actors of their options for 'exit' and 'voice' (Hirschman, 1993; Opp, 1994).

The Overthrow of Communism

While atypical of revolutions in many respects – for example, in their restorative character (Ash, 2009) – the uprisings that overthrew Communist regimes did involve mass uprisings from below, as well as a shift in the founding basis of state power and the accompanying ideology that had rationalized one-party rule. On the other hand, it was not entirely clear that the social basis of power had been fundamentally transformed, at least not in the ways envisioned by those who heralded these transitions as democratic revolutions. The shifts from centrally planned to market economies were often accomplished by opaque and corrupt processes of privatization, leaving concentrations of market power in the hands of the old party and state elites. In the former Yugoslavia, the collapse of the federal state was accompanied by the rise of ultranationalist demagogues and massive ethnic violence. The breakup of the former Soviet Union saw the emergence of corrupt and repressive autocracies in some of the Central Asian and Baltic states, violent conflict over ethnic separatist movements in Chechnya and Georgia, and in Russia itself a new centralization of power and restriction of liberties by Vladimir Putin through his United Russia party. Given these medium-term outcomes, it was debatable whether the uprisings that overthrew Communist regimes should be classified as revolutions, much less democratic revolutions.

Electoral ('Color') Revolutions

In the wake of the democratic setbacks in many post-Communist states, a revived wave of pro-democracy uprisings swept East-Central Europe, the Balkans, and the former Soviet Union beginning around 1996 and continuing into the 2010s. Variously labeled 'electoral revolutions' or 'color revolutions' after the emblematic colors that many of the movements adopted, these uprisings were characterized by coordinated mass protests against fraudulent elections and semi-authoritarian incumbents. They used innovative political symbolism to undermine the legitimacy of transitional post-Communist regimes that were still not fully institutionalized, and to signal (domestically and across countries) the degree of latent discontent in order to encourage others to overcome the barrier of fear. These movements received extensive external support and funding, notably from U.S. governmental, quasi-governmental, and nongovernmental 'democracy promotion' programs, leaving them open to nationalist accusations of Western meddling. The 2012 Russian election, in which Vladimir Putin claimed a sizable victory amid fraud and intimidation, once again raised questions about the scope and durability of the so-called color revolutions. The narrow focus on elections also cast doubt on whether the movements should be considered revolutions.

Rediscovering the Power of Nonviolence

One of the interesting developments in revolutionary movements of the late twentieth and early twenty-first centuries was the renewed salience of nonviolence as a guiding philosophy and/or strategy. Nonviolence political action had a long history, and it played a prominent role in successful social movements such as Mohandas K. Gandhi's struggle against British colonial rule in India in the early twentieth century and the U.S. civil rights movement led by Dr. Martin Luther King, Jr. in the 1960s. The techniques of civil disobedience and other nonviolence resistance were used by part of the South African anti-apartheid movement, particularly from the 1970s through the early 1990s; the Philippine 'People Power Revolution' against the dictatorship of Ferdinand Marcos in 1986; many of the uprisings against Communist rule in Eastern-Central Europe, such as the 1989 'Velvet Revolution' in the former Czechoslovakia; and as a defining feature of the 'color revolutions' from the late 1990s onward. The widespread use of nonviolent civil disobedience in the latter cases may reflect a process of political learning or diffusion of knowledge about the specific vulnerabilities of authoritarian regimes. Indeed, the lessons were deliberately transmitted by one of the foremost contemporary experts on nonviolent political action, whose primer on how to bring down a dictatorship became essential reading for protagonists of the 'color revolutions' (Sharp, 2010).

The notion of a nonviolent revolution seems counterintuitive, since the scope of social and political change inherent in the concept of revolution is almost certain to be intensely resisted by entrenched interests. However, the logic of nonviolent action is not passivity, but rather active confrontation against unjust authority, using techniques such as mass noncooperation to expose the latent structural violence of a system and thereby delegitimize it. Such action may in fact provoke state violence, in which case the opposition may refuse to respond in kind, calculating that the resulting increase in delegitimation will lead to regime collapse. Maintaining a disciplined commitment to nonviolence in such circumstances may be difficult, particularly in the absence of a unifying moral framework of principled nonviolence (such as Gandhi's teachings in India). In fact, many

nonviolent mass uprisings occur in a mixed context in which others have chosen to take up arms.

The post–World War II international system has been based on the principle of state sovereignty and noninterference in the domestic affairs of states, but shifting norms since the late twentieth century may be weakening the protections for authoritarian regimes and creating new openings for mass opposition mobilizing. One such shift is the expanding discourse and institutional framework of universal human rights, most actively promoted by international nongovernmental organizations. Another is the establishment in 2002 of the International Criminal Court to prosecute individual political leaders responsible for genocide, war crimes, or crimes against humanity. A third is the 2005 United Nations endorsement of a 'Responsibility to Protect,' a principle supporting international intervention against regimes committing atrocities against their own people. Given that structuralist theorists of revolution posit an international opening as one of the preconditions for revolution, these shifts along with the end of the Cold War could be part of the explanation for the apparent upsurge in democratic revolutions.

The 'Arab Spring'

Beginning in the spring of 2011, a wave of uprisings in the Arab world rocked some of the most seemingly entrenched autocracies in the Middle East and North Africa. Quickly labeled the 'Arab spring,' 'Arab uprisings,' or 'revolutions,' the protests were initially triggered by the actions of Mohamed Bouazizi, a 26-year-old Tunisian street vendor who set himself on fire after his fruit cart was seized by police. Massive demonstrations subsequently led to the ouster of the regimes of Zine al-Abidine Ben Ali in Tunisia, Muammar Qaddafi in Libya, and Hosni Mubarak in Egypt, as well as ongoing challenges to autocratic rule in Syria, Yemen, Bahrain, and elsewhere in the region.

In seeking to explain these events, structuralist theorists of revolution highlighted the particular susceptibility of personalist or 'sultanistic' regimes to mass opposition organizing. The rapid demographic growth of young, urban, educated populations who were unemployed or underemployed (like Bouazizi, in the informal sector) was cited as another causal factor, aggravated by rising food prices. The class dimension of these uprisings was most evident in Egypt, where workers played a key role in organizing strikes and protests. One structural variable affecting regime survival was the extent of defections among marginal elites, particularly the military, who were sometimes offended by the extreme concentration of wealth and the personal corruption of the rulers.

While the clustering of these uprisings suggested some common causal factors, the motivating grievances and ideological framework differed considerably among the participating groups. There were significant differences between militaries, secular liberal democrats, and Islamists (e.g., Egypt); as well as divided ethnic or religious sectarian (Syria) and tribal (in Libya and Yemen) loyalties and coalitions. Further complicating the outcomes, external actors had varying agendas and degrees of involvement. The U.S., for example, quietly supported NATO intervention on behalf of rebels in Libya, acquiesced to the overthrow of its longtime client Mubarak in Egypt, but backed Saudi use of force against the opposition in Bahrain. Russia and China used Security Council vetoes to block UN coercive action against the Syrian regime's use of violence against opponents. Typically of revolutions, the outcomes were indeterminate: not all resulted in successful transfer of state power, and new regimes did not necessarily reflect a stable consensus of values among those who had joined the mass mobilization. Once again, democracy was not a guaranteed outcome.

One notable feature of the Arab uprisings was the significant participation of youth and women. Women made up about a third of the direct participants in the protests that brought down Mubarak's regime in Egypt. A Yemeni democracy activist, Tawakul Karman, in 2011 became the first Arab woman to win a Nobel Peace Prize. High unemployment was one factor motivating the extensive participation of youth in the protests. Another characteristic of the uprisings was the prominent use of social media (such as blogs, Facebook, and Twitter) for communication and coordination among protesters and their networks of supporters (*see* New Media and Democracy in the Arab World). These technological innovations were more facilitators than causes and did not erase national cultural specificities (Norris and Inglehart, 2011), but they did highlight the ways in which rapid interconnectedness has eroded the relevance of many boundaries and allowed more fluidity in the creation of cognitive communities (Castells, 2012). The imagery, branding, and tactics of the protests spread with startling speed. At the same time, the rapidity of communication can lead to misperceptions, and the plugged-in social sectors may not be representative of the general population. Moreover, just as the rapid transmission of information can fuel a spreading wave of revolution, it can also generate a backlash or preventive measures (for example, in the responses to the Arab uprisings by the governments of Russia, China, and Saudi Arabia).

Rethinking Revolution in the Context of Globalization

Globalization, or the compression of time and space, has reshaped many aspects of the contemporary political world. Alongside states, other axes of power include transnational corporations, global and regional trade regimes, and international financial institutions. Counter-hegemonic or antisystemic globalization-from-below now includes a variety of transnational social movement networks, as well as shifting focal points for the growing 'alter-globalization' movement, such as the World Social Forum of civil society organizations inaugurated in Brazil in 2001, and global protests such as the clashes at the 1999 World Trade Organization (WTO) ministerial meeting in Seattle, and the 2001 summit of the Group of 8 (G-8) industrialized countries in Genoa. The shift in the capitalist world system from the Fordist regime of capital accumulation based on industrial mass production, to a regime of flexible accumulation and globally mobile capital, has been accompanied by the rise of a new regulatory framework of global institutions governed by neoliberal ideology and the emergence of a transnational capitalist class. These changes call for rethinking the concept of revolution (Foran, 2003), as the spaces of contestation move from the state to the world system.

World-systems theory suggests that revolutions should be defined not as discrete phenomena of nation-states, but rather as transformations in the world system (Boswell and Chase-

Dunn, 2000). From this perspective, an interconnected wave of upheavals such as the Arab spring or democratic revolutions can be understood as part of an uprising against the global system. In an influential work, Hardt and Negri (2000) argue that the era of competition among imperialist powers has been replaced by a unitary structure of power they call Empire, a kind of transnational network capitalism which has increasingly privatized public space and reduced the scope for conventional political participation. They argue that Empire actually creates greater potential for revolution, but that instead of a class rising up to seize state power, it will take the form of 'the multitude' resisting the disciplinary regime of global capital through alternative cultural and economic movements.

A possible example of this new way of conceiving revolution would be the Zapatista rebellion of 1994, triggered in part by Mexico's integration into the global capitalist economy as symbolized by entry into the North American Free Trade Agreement. While claiming the right to community-based autonomy from the state, the seemingly local Zapatista movement also challenged the larger logic of subordination to the dictates of global capital, in ways that inspired global networks of resistance. The Zapatista focus on direct participatory democracy, and on connecting such concepts as community-based autonomy, solidarity, and the commons to a critique of global capitalism, served as an inspiration for the emblematic 1999 Seattle WTO protest and many other 'alter-mundista' or 'alter-globalization' movements.

Such antisystemic movements focus more on transforming social relations than on overthrowing the state. Holloway (2002) has suggested a new meaning of revolution, arguing that it is possible and necessary to change the world without taking power, at least in the traditional state-centric and hierarchical understandings of power. Postcolonial and feminist theories have introduced the notion of empowerment as opposed to power-over, and also questioned the hidden power relations in the way concepts are constructed and knowledge is produced. Holloway's thesis remains controversial as states continue to wield conventional forms of power, but it is evocative. At the end of the Cold War when Nicaragua's revolutionaries made history by turning over the state power they had won through insurrection in 1979 after losing elections in 1990, Sandinista leader Daniel Ortega vowed they would 'govern from below.' This vision, albeit unrealized, suggested a new way of thinking about where the essence of a revolution is found, i.e., in empowerment that is constructed within society. The demise of state socialism in Eastern-Central Europe also fueled the global quest for radical democratic alternatives, rooted in autonomous action within civil society.

As globalization undermined territorial definitions of social and political organization, shifting decision-making authority to transnational structures, revolution seemed less about seizing state power. From the Internet-savvy Zapatista rebels of Chiapas, Mexico, to the transnational anti-sweatshop movement and the 1999 Seattle protest against the WTO, there were intriguing signs of an emerging global civil society. The global economic crisis beginning in 2008, with a potentially catastrophic environmental crisis looming in the background, was accompanied by a series of worldwide protests including the '*indignados*' of Spain, anti-austerity uprisings in Greece, student protests in Chile and Mexico, and the Occupy movement that began on Wall Street and quickly spread. All of these mobilizations were directed at global forces and not just the nation-state, and all sought to reclaim the commons from the encroachment of centuries of global capitalism. These new forms of resistance against corporate-dominated globalization stretched the boundaries of existing concepts of 'revolution.'

Revolution, Theories of

Rod Aya, Amsterdam, Netherlands

Abstract

Revolution has different meanings, and theories of revolution do not all explain the same facts. Some theories explain revolution in the sense of a revolutionary movement – an attempt to change government, regime, society, or all three by violence. Others explain revolution in the sense of a revolutionary outcome – a successful change of government, regime, society, or all three by violence. Still others explain revolution in the sense of a revolutionary situation – a contest for state power by violence. But all theories of revolution shortlist explanatory causes and validate the explanation with case histories or statistics to show by the comparative method that where these causes occur, a revolution (by some definition) occurs as well and that where they do not occur, revolution (by that definition) does not occur either. Grouped by causes they cite, theories of revolution make up four types – psychological, functional, structural, and political. Psychological and functional theories mostly explain revolutionary movements; structural theories mostly explain revolutionary outcomes; and political theories mostly explain revolutionary situations. Theories of revolution are contentious, but few controvert the ancient wisdom that revolution needs hope of success and that hope feeds on a weak government torn by faction.

Theories of revolution are (or purport to be) causal explanations of revolution. They say if certain sufficient conditions (the causes) occur, then revolution (the effect) will occur as well. But *revolution* has different meanings, and theories of revolution do not all explain the same facts. Different theories explain different facts as well as cite different causes – different circumstances or situations that (by hypothesis) motivate or constrain people to commit revolutionary violence (Aya, 2001). Before analyzing theories of revolution and the why-question they address, therefore, one must distinguish between the different social facts those theories would explain – the different historical events *revolution* refers to.

Definition

Revolution (as used in the theories-of-revolution literature) has three different meanings – it denotes three different kinds of social fact or historical event that theories of revolution would explain: a revolutionary movement, a revolutionary outcome, and a revolutionary situation. Examples document the claim that *revolution* is defined these three ways.

Revolution in the sense of a revolutionary movement is a concerted effort to change government, regime, society, or all three by violence. By one definition it is "internal war" (Eckstein, 1965) – an attempt by "subordinate groups" to change government, policy, regime, or society by violence (Zagorin, 1982, 1, p. 17). By another definition it is an attempt to "establish a new moral and material world and to impose, or evoke, radically new patterns of day-to-day conduct," again by violence: "A holy commonwealth, a republic of virtue, a communist society – these are the goals revolutionaries seek" (Walzer, 1998, p. 128). Replacing "subordinate groups" with "revolutionaries," this definition includes new rulers like the Committee of Public Safety behind the Terror when the revolution was "in the government, not in the populace" (Palmer, 2005, p. 294). With that, *revolution* meant new regime (Malia, 2006) – save in Japan where the new regime called itself the Restoration.

These definitions highlight revolutionary violence as the chosen means to a wanted end in accord with the view that social action makes sense no other way (Weber, 1968; Coleman, 1990; Popper, 2002). But by neither definition must a revolutionary movement succeed in order to be called a revolution – it can fail like the Committee of Public Safety doomed by faction ramified through the Convention, the revolutionary legislature that elected it (Palmer, 2005).

Revolution in the sense of a revolutionary outcome is a successful change of government, regime, society, or all three by violence. By a venerable definition it is a "violent transference of power and property," that is, a "seizure of power and redistribution of property" (Syme, 1939, pp. vii, 2). By newer, more ambitious definitions it is a "rapid, complete, and violent change in values, social structure, political institutions, governmental policies, and social-political leadership" (Huntington, 1968, p. 344); a "violent, fundamental, and abrupt change of incumbent elites, status and class relations, institutions, values, symbols, and myths" (Mayer, 1971, p. 47); or a violent change of "status and power, … economic organization and property ownership, and … symbols and beliefs that justify the distribution of power, status, and wealth" (Goldstone, 1991, p. 11). And by a narrower definition confined to "successful social revolutions," it is "rapid, basic transformations of a society's state and class structures … accompanied and in part carried through by class-based revolts from below" (Skocpol, 1979, p. 4).

Success is crucial – revolution is a misnomer unless revolutionaries "win state power and use it to effect a major property transfer" (Gouldner, 1979, p. 9) plus whatever else the definition of revolution as a revolutionary outcome stipulates, say, a "complete redesign of state, society, economy, and culture" (Pipes, 1991, p. xxi).

Revolution in the sense of a revolutionary situation is a contest for state power by violence. By one definition it is "dual power," that is, a "trial by battle" where government and

opposition "split the state superstructure" (Trotsky, 1977, pp. 223–232). By another definition it is "multiple sovereignty," which starts when the opposition rules people nominally subject to the government and ends when it defeats, succumbs to, or cuts a deal with the government (Tilly, 1978, pp. 189–222). By other, convergent definitions it is a "revolutionary political crisis" (Skocpol, 1979) or "state breakdown" (Goldstone, 1991) where civil war decides sovereignty.

A revolution in one sense can occur without a revolution in both other senses occurring as well. A revolutionary movement can occur without a revolutionary outcome occurring because revolutionaries can lose like the Taiping Tianguo whose civil war with the Qing regime killed about 20 million people (Jen, 1973). A revolutionary outcome can occur without a revolutionary situation occurring because the new government in power can make a "revolution from above" like Stalin whose collectivization of farming and party purge also killed about 20 million people (Conquest, 1990) and because revolutionaries can take power legally like Hitler (Turner, 1996) whose agents killed about that many civilians – roughly a third of them Jews (Davies, 1997) – in World War II, showing what a "fanatical movement" atop a "well-organized state" can do (Sheehan, 2008, p. 154). And a revolutionary situation can occur without a revolutionary outcome occurring because the government can win or else make a deal as in Central America where "socialist revolution from below" led to a "transition to democracy" (Paige, 1997, p. 358). But neither a revolutionary situation nor a revolutionary outcome can occur without a revolutionary movement occurring because they both entail revolutionary violence, which is organized violence, that is, collective action – no big-time dirty work without motivated, coordinated perpetrators (Aya, 2001).

These three meanings of revolution accord with social science usage, which calls a change of government by violence a coup d'état; a change of regime as well as of government by violence a political revolution; a change of society as well as of government and regime by violence a social revolution; and a contest for state power by violence a civil war (Huntington, 1968; Skocpol, 1979; Walzer, 1998).

But social science usage is misleading if it suggests the social facts or historical events referred to are mutually exclusive. A coup d'état can become a political revolution, and a political revolution can become a social revolution – if the new government decides to make "revolution from above" (Colburn, 1994). Indeed, a social revolution is a change of society by violence the new government itself mainly commits: Red Terror, War Communism, collectivization, and the Great Terror in Soviet Russia were all "willed by the rulers" or their dominant faction (Kolakowski, 1978, 3, p. 157); ditto land reform through revolutionary terror, collectivization, the Great Leap Forward, and the Cultural Revolution in Communist China (Schurmann, 1968). And a civil war that gives both radical revolutionaries and parochial rebels a fighting chance – and is won by whatever side best exploits what Machiavelli called *virtù* and *fortuna* – can start when counterrevolutionaries (Mayer, 1971) subvert or usurp the government "not to make revolution but to avert one" (Pipes, 1995, p. 490).

Theories of revolution that would explain a revolutionary movement or a revolutionary situation need not explain a revolutionary outcome, but theories that would explain a revolutionary situation, a revolutionary outcome, or both have to explain a revolutionary movement as well. And whatever the facts that theories of revolution would explain, those facts entail violence – the willful infliction of physical harm. Burke and the Bolshevik ideologists who dismissed nonviolent revolution as a contradiction in terms conformed to social science usage – no violence, no revolution, by any definition (Johnson, 1982). Theories of revolution converge on the modus operandi – revolutionary violence. The question they would answer is what motivates revolutionary violence and what consequences – anticipated and intended or not – follow from committing it.

Explanation

Theories of revolution in Western social science date back to the Greeks, who viewed revolution as the worst kind of war (Plato *Laws* 629d). Thucydides blamed revolutionary situations with or without revolutionary outcomes on revolutionary movements or conspiracies (as he called them) and blamed those conspiracies on hope of success (*Peloponnesian War* 3.45). Plato agreed and blamed hope of success on weak government torn by faction (*Republic* 465b, 545d), which he would eliminate from his ideal polity by abolishing the family and private property among the rulers – no faction, no revolution (*Laws* 683e). Aristotle added on the widest though not deepest comparative study that since hope along with faction springs eternal, no regime is immune to revolution (*Politics* 5).

The theory that people attempt revolution because they have hope of success, and have hope of success because they think the government is vulnerable, lived on in classic political sociology as an explanation of what to avoid and how to avoid it. Machiavelli, who wrote in effect the first handbook on coup d'état and counterinsurgency, told usurpers how to use force and fraud in order not to be overthrown in turn (*Prince* 17–19). Hobbes, trusting more to organization than to statecraft, designed a regime that would prevent "change of governments by civil war," that is, "attaining sovereignty by rebellion," by repressing "factions or conspiracies" (*Leviathan* 31, 15, 22) – small wonder his first published work was a translation of Thucydides. His take on the English Revolution *Behemoth* asked: Better not to kill 1000 seditious preachers than suffer 100 000 fatalities? *The Federalist* echoed Hobbes on sovereignty but held that checks and balances could avert faction and rebellion as well as tyranny. Burke – who predicted the regicide two years, the Terror three years, and the military dictatorship nine years in advance (O'Brien, 1993) and who in *Reflections on the Revolution in France* excoriated the revolution in its "moderate" phase – observed that the revolutionary legislature usurped a king out for compromise: "Their resistance was made to concession; their revolt was from protection; their blow was aimed at an hand holding out graces, favours, and immunities." Tocqueville summed up the whole line of thought: "The evil you would suffer patiently as inevitable seems unbearable as soon as you conceive the idea of escaping it" (*Old Regime and the Revolution* 3.4).

Not all theorizing on revolution was counterrevolutionary. "Violence is the midwife of every old society pregnant with a new one," wrote Marx (*Capital* 1. 24), though his instant

histories of revolutionary situations autopsied abortions and his class-conflict theory of revolutionary movements and their abortionists proved false – street fighters on both sides of the barricades in June 1848 in Paris, for instance, not only had the same class background but were a cross section of the manual workforce (Traugott, 2002). The theory explained history no better elsewhere – industrial workers neither launched the revolutionary movement nor achieved the revolutionary outcome the theory predicted. In Germany they did not even try, and in Russia they acquiesced as a revolutionary movement of Marxist intellectuals achieved a revolutionary outcome in their name by a military coup d'état – the October Revolution was so low profile that the author of *Ten Days That Shook the World* slept through it – followed up with Red Terror and Civil War, which plus famine and disease killed almost as many people as all belligerents lost soldiers in World War I (Moore, 1978; Pipes, 1991, 1995; Ferguson, 1999). But for the vicarious, posthumous fame Marx got from that much-imitated revolutionary movement whose ideology and terror made him a household word – the body count of Communist regimes may exceed that of both world wars combined (Courtois, 1999) – only intellectual historians might have heard of him today.

Whether counterrevolutionary or revolutionary, theories of revolution were handmaidens to political sociology and historiography before the twentieth century, when – with the revolutions attending both world wars – they hived off as answers to the why-question of revolutionary violence. The chief theorists were not activists but academics because activists propounded only trite theories of revolution consisting mainly of prophecy and propaganda: Trotsky (1977) – a seeming exception much admired by political sociologists (Stinchcombe, 1978; Burawoy, 1989) – stands out through historical detail (tendentiously reported and teleologically framed) plus brazen avowal of force and fraud; his prophecies, moreover, all proved false (Kolakowski, 1978). When activist theorizing rose above agitprop to consider strategic means and ends, it rehearsed the classic wisdom in reverse and advised revolutionaries to exploit faction in order to weaken the government and thereby raise hope of success. Whether more activists became revolutionary dictators (or their adjutants) than academics became theorists of revolution is moot – academics launched a social science growth industry (Gurr, 1980; Rule, 1988; Kimmel, 1990; O'Kane, 2000; Malia, 2006; DeFronzo, 2007; Zimmermann, 2011).

Academic theories of revolution, in the standard pilgrim's progress view, went through three stages of development since the 1920s. First there were natural histories (Edwards, 1970; Brinton, 1965) explaining recurrent sequences of similar events in "great" revolutions by the reasons that experts say motivated the people who made them but not generalizing the reasons into a causal theory. Then there were general theories (Davies, 1971; Feierabend et al., 1972; Smelser, 1962; Johnson, 1982) explaining revolutionary violence by discontent – due to frustration, relative deprivation, strain, or dysfunction – but explaining history ad hoc if at all. Now there are comparative-historical theories explaining select revolutions by "structural conditions" of state and society (Skocpol, 1979, 1994; Goldstone, 1991; Wickham-Crowley, 1992) – admixed with political culture (Goodwin, 2001; Foran, 2005) – cogently enough that older theories look passé.

The standard view is not totally false but ignores obvious continuities of theory and method. Theories of revolution since classical antiquity all cite a short list of sufficient conditions or explanatory causes – situational constraints or reasons that motivate people to commit revolutionary violence – and validate (or rather illustrate) the explanation with factual evidence consisting of case histories or statistics laid out to show by the comparative method (Ragin, 1987) that where the explanatory causes occur, revolution (by some definition) occurs as well and that where the explanatory causes do not occur, revolution (by that definition) does not occur either (Aya, 2006). The same goes for theories of collective violence generally as one lucid analyst (Rule, 1988) makes clear.

Grouped by the explanatory causes they cite, theories of revolution form four families – psychological, functional, structural, and political theories. As a rule, psychological and functional theories explain revolutionary movements – they explain why people attempt to change government, regime, society, or all three by violence; structural theories explain revolutionary outcomes – they explain why people successfully change government, regime, society, or all three by violence; and political theories explain revolutionary situations – they explain why people fight civil wars for state power. Psychological and functional theories that explain revolutionary movements mostly leave revolutionary situations and revolutionary outcomes to historians while structural theories that explain revolutionary outcomes also explain (or at least note) revolutionary situations and revolutionary movements along the way, and political theories that explain revolutionary situations explain (or at least note) revolutionary outcomes and revolutionary movements in passing.

Psychological theories explain revolutionary movements by discontent due to frustration alias relative deprivation – defined as perceived discrepancy between what people want and expect and what they get. These theories all assume the frustration–aggression principle that people who are frustrated will commit aggression against the perceived source of frustration, but they disagree about what social facts arouse frustration – one blames steady improvement followed by a sudden setback that raises expectations but reduces attainments; another blames rapid social change that raises expectations beyond attainments; yet another blames whatever raises expectations, lowers attainments, or both. Few psychological theories explain revolutionary violence by discontent alone, however – most add insurgent strength and government weakness to their short list of sufficient conditions (Davies, 1971; Gurr, 1970; Feierabend et al., 1972).

Functional theories explain revolutionary movements by discontent due to strain, dysfunction, or disequilibrium – defined as discrepancy or dissociation between socially prescribed ends, goals, or values and institutionally available means, procedures, or norms for attaining them (Merton, 1968). When social change creates a gap between ideology and experience that the government is unwilling or unable to close with reform, people turn to revolutionaries for salvation. If the government looks weak or loses control of its armed forces so the revolutionaries think they can

overthrow it, revolutionary violence erupts (Smelser, 1962; Johnson, 1982).

Structural theories explain revolutionary outcomes piecemeal – they explain first why power elites subvert or usurp governments, then why subalterns rebel, then why radical vanguards seize power, and then why new rulers reconstruct state and society. The first two events constitute revolutionary situations; the last two constitute revolutionary outcomes. Each event depends on the one that precedes it – path dependency is the buzzword: no subversion or usurpation, no rebellion; no rebellion, no power transfer; no power transfer, no revolutionary reconstruction. These events comprise collective actions and reactions, which the theories explain as rational efforts to satisfy interests (Coleman, 1990) under structural constraints like government weakness, folk community organization, vanguard politico-military competence, and geopolitical exigency. Ideology is a charter for vested interests – the motivating situational constraints are structural (Skocpol, 1979, 1994; Goldstone, 1991).

Political theories likewise explain revolutionary situations piecemeal – they explain first why insurgents claim sovereignty, then why certain people choose to support them, and then why the government fails to repress the insurgency. Revolutionary situations do not all have revolutionary outcomes but some do, and political theories likewise explain these outcomes piecemeal – they explain first why government supporters defect, then why insurgents gain armed force, then why government forces defect, and then why insurgents oust incumbents. Popular support and armed force are much the same thing – revolution is not an election but a gang war where all sides exchange protection for obedience (Aya, 2005). These events again comprise collective actions and reactions, which political theories explain as rational efforts to satisfy interests (Coleman, 1990) under political and strategic constraints like organization, armament, threat, and opportunity. Ideology again is a charter for interest – the motivating situational constraints are political and strategic. Whether and to what extent new rulers reconstruct state and society is another question, which political theories mostly leave to historians (Tilly, 1978, 1993). Nasty aftereffects of revolution like war and genocide are explained as a rule in political terms (Walt, 1996; Melson, 1992).

Theories that explain revolution piecemeal are cumulative causal models (Stinchcombe, 1978) whose elements are people out to make the best of their situation as they see it over time. Previous choices constrain subsequent choices like moves in a game – *échanges de coups* (Dobry, 2009) – save revolution is a most dangerous game played for keeps where players get killed. Between revolutionary situations and revolutionary outcomes involving revolutionary movements falls the shadow of contingent history comprising strategic interactions.

These family portraits of theories of revolution are not just composite sketches, they are caricatures. But caricatures accentuate real features: psychological and functional theories explain revolutionary violence in general; structural and political theories explain revolutionary violence in history and the consequences of committing it – whether anticipated and intended or not. Matching general theory and historical fact (Merton, 1968) is vexing enough that a standard work on violent strife in "developing societies" (Huntington, 1968) cites psychological theories of revolution in one chapter but sets out a political theory of revolution in another that ignores them completely, using "frustration" to mean thwarted satisfaction of specified vested interests.

To sum up: revolution (the effect to be explained) is a social fact or historical event that (by whatever definition) entails violence used to change government, regime, society, or all three; the conditions or circumstances under which it occurs (the causes) are the situational constraints or reasons that motivate people to commit revolutionary violence; and theory of revolution (like all empirical theory) needs independent evidence besides the fact or event to be explained or else the explanation is circular – it doesn't do to say something is the cause of an effect when the only evidence for the explanation is the effect itself (Popper, 1979).

Validation

Theories of revolution are contentious and have been ever since Aristotle (*Politics* 5) attacked Plato's ideal-type model of regime change, which applies his faction-in-government theory of revolution – based on Thucydides and captive fieldwork (Aya, 2005) – to ideal cases: aristocracy, timocracy, oligarchy, democracy, tyranny (*Republic* 8). Aristotle rejected the model but took the theory for granted. Plato's relentless modern critic Popper (2002) thought the model a brilliant situational logic of power politics (especially tyranny) and the theory true. And so it goes. Disputes over theories of revolution are like strife among factions where (as Gibbon says) the contenders suffer what they would inflict.

Structural theory advocates point out that psychological and functional theories explain neither revolutionary situations that start because power-elite infighting paralyzes governments nor revolutionary outcomes that see new regimes more bureaucratic and tyrannical than the old (Skocpol, 1979, 1994; Goldstone, 1991). Political theory advocates point out that revolutionary outcomes depend on the fortunes of war in revolutionary situations – structural *virtù* proposes, political *fortuna* disposes (Tilly, 1993). Skeptics add that since revolutionary outcomes owe to actions revolutionaries take because they expect these actions to yield great benefits that often do not materialize (Hirschman, 1977) no theory that downplays ideology can explain revolution credibly (Aya, 1990, 2001, 2005). How else to explain strategic decisions like Lenin's based on false expectations of imminent world revolution, the rage for socialism in "developing" countries ruled by Marxist radicals, and the resort to mass terror by revolutionary regimes in proportion to the transformation they attempt and the resistance they meet (Pipes, 1991, 1995; Colburn, 1994; O'Brien, 1993; Mayer, 2000)?

Nor is this all. Revolutionary situations involve *mobilisations multisectorielles* (Dobry, 2009) where "grass roots" join the fray for reasons of their own and may even fight the new regime as in France and Russia (Pipes, 1991, 1995; Mayer, 2000). Mobilizing "grass roots" rank and file in revolutionary movements can be difficult, moreover, as in China and Vietnam (Hofheinz, 1977; Benton, 1992, 1999; Race, 2010; Popkin, 1979). In revolution as in war, the multi-person prisoner's dilemma alias free-rider problem where each is tempted to let everyone

else do the dirty work makes individual rewards for helping out and punishments for holding out imperative (Olson, 1971; Lichbach, 1995).

Structural and political theories mention but do not always explain these facts, which embarrass psychological and functional theories. Another embarrassment is that revolution is the work of militant minorities (Coleman, 1990, p. 489) including "grass roots" whose opportunity owes to government weakness, toleration, or support. Political opportunity *structure* – the trademark idea of the social movements literature (Tarrow, 1998) – is really political opportunity *conjuncture*: it can change overnight. The *sans-culottes* (iconic social movement and "grass roots" militant minority par excellence) are paradigmatic:

> If, for a very short period, the *sans-culottes*, taken together, represented a national force, it was because the Jacobins needed such a force for their own purposes. The true isolation of the *sans-culottes* is demonstrated in the conditions of the year III, when, far from enjoying the support of the governing class, they were actively persecuted by the Thermidorians. The *sans-culottes* were then revealed as completely powerless and also very unpopular.
>
> Cobb, 1970, p. 335

If the volcanic model of revolutionary violence as an eruption of anger or mass temper tantrum (Aya, 1990) were remotely true, this item of strategic analysis by a virtuoso historian would make no sense at all. Revolutionary violence entails armed force whose management decides revolutions – two cheers for Chorley (1973).

The bane of explaining revolution, however, is circularity. A methodological object lesson – the sea is rough today because Neptune is angry as shown by its being rough as ever when Neptune is angry (Popper, 1979, p. 192) – applies to theories of revolution where the fact to be explained is the only evidence for the explanation. The fallacy involves either imputing motivation for revolutionary violence without evidence that people who gang up and kill have this motivation or else claiming that invidious conditions of state and society *cause* revolutionary violence without evidence that these conditions motivate people to gang up and kill – no evidence that those who commit the violence do it in order to remedy these conditions.

Psychological and functional theories are flagrant offenders. Psychological theories explain revolution by discontent due to frustration alias deprivation but cite no evidence of the alleged "root cause" except aggregate data on social conditions presumed to create discontent. Functional theories explain revolution by discontent due to strain, dysfunction, or disequilibrium but cite no evidence of the alleged "root cause" except reports on social conditions presumed to create discontent, which is anyway not enough to motivate revolutionary violence (Aya, 1990).

Structural theories of revolution are scarcely immune. One blames "state breakdown and revolution" on "political stress," the combined result of "state fiscal distress," "elite mobility and competition," and "mass mobilization potential," all due to "population pressure." Rapid population growth causes price inflation, straining government budgets and reducing real wages; intensifies job competition among power elites; fills urban areas with young people – and so stresses political institutions till revolutionary violence erupts (Goldstone, 1991). The facts cited to support the theory – aggregate data on social conditions that allegedly cause revolutionary violence – include no evidence that those who commit the violence do so in order to change these conditions – no evidence that they gang up and kill in order to get jobs or boost wages (Aya, 2001).

Another validation issue is empirical – whether case histories put forward to confirm some theoretical explanation by the comparative method actually do so. Take the "most influential book in the field and for many already a classic" (Malia, 2006, p. 310) – to quote a dissenting historian. It says "successful social revolutions" have "distinctive, long-term, structural causes," namely, "state breakdown" plus subaltern "solidarity and autonomy" – so when elites usurp the government, subalterns rebel, letting radicals seize power and reorganize society (Skocpol, 1979, pp. 5, 295; 1994, p. 5). The second "structural" cause does not turn up in all cases examined but what does turn up – radicals seizing power and reorganizing society – is neither "distinctive," "long-term," nor "structural." Worse, "successful social revolutions" since World War II share no prior "structural conditions" besides weak government torn by faction but see radical vanguards take what they think is a shortcut to power and prosperity (Colburn, 1994). With that, the comparative method empirically refutes the theoretical explanation it supposedly confirms (Aya, 2006).

"Boolean" charts associating hypothesized causes and reported effects – their presence or absence indicated by 1 or 0 (Ragin, 1987; Wickham-Crowley, 1992; Foran, 2005) – leave these validation issues untouched.

Theories of revolution remain contentious, but few controvert Thucydides that revolutionary movements need hope of success or Plato that hope feeds on weak government torn by faction. A landmark treatise on social theory has a chapter on revolution (Coleman, 1990, pp. 466–502) that reinvents their explanation and applies it variously without acknowledgment, or even awareness. The wisdom of the ages on explaining revolution is no less wise for being ancient.

Revolutions of 1989–90 in Eastern Central Europe

Abstract

The revolutions in Eastern Europe were different from former revolutions because – with the exception of Romania – never have such radical changes been achieved with so little violence from below and from above. Eastern Europe proved to be a deviant case in the history of revolutions for other reasons too, which are discussed here. The special nature of the 'velvet revolutions' is discussed, touching on the role of elites, the international situation, and the loss of regime legitimacy. Three models of system change that occurred during 1989 are offered, and consolidation of these peaceful revolutions is discussed.

A Deviant Type of Revolution

The revolutions in Eastern Europe were no conventional changes of the system that can be dealt with in the tradition of sequence models. There was no uniform anatomy of the changes, though never in European history have so many regimes collapsed at the same time and for similar reasons. Revolution has traditionally been linked to violent change that made it different from coups d'état. Nevertheless, the depth of their change, made the events between 1989 and 1991 both a political and a social revolution at the same time. In this respect it was comparable only to the Bolshevik revolution of 1917 and its later repercussions in the formation of 'people's democracies' after 1945 in the realms under the influence of the Red Army.

No former system's change was as burdened with the same problems of institution-building as this one. Authoritarian and Fascist dictatorships may have changed political institutions, but they hardly touched the system of stock markets and banks. There was no need in post-authoritarian regimes to create offices to administer unemployment insurance or institutions for social security.

This process of transformation was so unique that the old notions of revolution and reform tend to be inappropriate. Perestroika in the Soviet Union was frequently compared to the politics of Peter the Great, the Meiji Revolution, or the innovations of the Young Turks in the Ottoman Empire. Reform was defined as an eclectic 'un-ideological' process of 'un-dogmatic' actors. Its consequences were contradictory measures and even 'messiness' of reform. Because it was initiated from the top level of Soviet power, Perestroika can also be classified as a reform from above, steered by the ideological thrust of a great leader.

In Gorbachev's self-perception, Perestroika was a revolution. The old Soviet Union under Brezhnev started to accept rather loose talk about revolutions. Revolution lost its connotation of a process initiated by political elites and by political means. It was watered down to processes that the Central Committee and the Politburo of the party were no longer able to control, and thus demographic, environmental, and technological revolutions entered the discourse in Communist countries. Gorbachev tried to use the concept of revolution in a more political way. Perestroika was dubbed a 'second revolution' and Gorbachev hinted at Lenin, who had already envisaged several revivals of revolutionary activities in the tradition of the great French Revolution that failed to implement its goals in one coup and had to be repeated in 1830, 1848, and 1871. Western analysts, on the other hand, never used the term 'revolution' in describing the process of Perestroika.

The reforms in Eastern Europe were different from former revolutions because – with the exception of Romania – never had such radical changes been achieved with so little violence from below and from above. Eastern Europe proved to be a deviant case in the history of revolutions for several reasons:

Political modernization was achieved in two different phases. The system's change was a second attempt at modernization after the Socialist attempts in 1917 and 1945.

The collapse of Socialism resulted from a threefold dissatisfaction in East European populations: dissatisfaction with a repressive political system, with an inefficient economic system, and with the dominance of hegemonic ethnic groups within a federation (Russians, Serbs, and Czechs) or within the Socialist camp (the Soviet Union vis-à-vis its satellites).

There was not the same continuity of periods as in Southern Europe in the 1970s with phases such as liberalization, democratization, and consolidation.

The new process of transition was burdened with the unique double task of transforming both the political and the economic system at the same time, something which has never before happened in world history.

The new transition process was hampered by ethnic strife. Spain had experienced some of it, but managed to solve the problem by various concessions of autonomy to ethnic groups.

In former transitions, a new elite was ready to take over power. There was no real preparation for the new task in Eastern Europe. Even non-Marxist scholars sometimes believed in Marxist 'periodization' schemes. They held that a system needed to develop an economic basis and a recruiting ground for the new political elite. The old regime developed the preconditions of change. Revolution was only the last blow for the old system. The simplicity of this concept of transitions did not even work in the great French Revolution. Historians have shown that the French Revolution did not abolish feudalism or establish a market society throughout the country. This process of accomplishing a true market society was not successful before the beginning of the Third Republic (1875ff.).

Reasons for the Velvet Revolutions

In the history of changes of regimes, the leadership groups have frequently become disunited, and one part of the power elite then started mobilizing the masses. In Eastern Europe, this model did not apply. The elites remained quiet until the last moment. The technical intelligentsia did not develop into an opposition to the 'strategic clique' in power. The technical intelligentsia increasingly de-ideologized and created more room for maneuvering in its own field, independent of political leadership. It avoided conflict, however.

Reformist elites in those Socialist systems where the regime eroded slowly, negotiated to initiate revolution and thus avoided the necessity of appeal to the masses. In Hungary, the negotiated revolution took place with complete discipline and there was no unified counter-elite. In Poland, Solidarity could have been the counterforce, but in the last stage it was pressed by the people rather than by a leadership directing the masses into conflict with the 'nomenclatura' leadership.

Only in Romania – in the third model of a collapse of the system, but under control of a middle-level elite of the old regime – was there conflict among elite sectors. The military, after some wavering, finally sided with the protest movement, not so much because of ideological sympathies with the revolutionaries, but because of its rivalry with the Securitate armed forces. The military played the role of a rear guard – derogated by Lenin as '*chvostizm*' – but apparently the capacity to wait and see and to grasp the right moment for action in the rear guard is not always a negative feature, as Lenin supposed.

The European Fascist dictatorships collapsed in 1945 because they were defeated in war. In Southern Europe and Latin America external factors contributed to the collapse of regimes (Greece, Portugal, and Argentina). In Eastern Europe, changes in the international situation facilitated the peaceful velvet revolutions. The Soviet Union still existed as a hegemonic power, but Gorbachev had indicated that the satellites could no longer rely on Soviet help in a case of internal strife. It was less the active behavior of a superpower, and more the 'non-decisions' of the hegemonic bloc power that did not intervene, which caused the collapse of the whole alliance. Theoretically, each national elite could have followed the Chinese example of bloody suppression. Why did this not happen?

The most important reason is again the international factor: the 'Brezhnev doctrine' was meant to strengthen weak regimes within the bloc. But the bloc center at Moscow was not prepared for a situation where all the leaderships of her satellites entered into troubles at the same time. The Brezhnev doctrine proved its dysfunctional consequences. It had spoiled the satellite leaderships who were always able to rely on Big Brother's tanks. Romania was the only deviant case which did not recognize the doctrine and therefore had to provide for her own security. All of the other governments were not accustomed to organizing big actions for their own security and caved in as soon as the masses confronted them directly.

The old regime in its last defensive stage pretended that the turmoil was caused by subversion from the 'imperialist powers'. This was wrong, since the Western powers were so accustomed to détente that they avoided direct actions for destabilizing the Communist systems. It was not international but rather transnational policies which contributed to the destabilization of Communism from outside. The protest movements in the streets of Leipzig did not receive weapons, but instead got information from the Western media about the situation in the country, the counter-reactions of their leadership, and the points of rally of the protest movement.

The international factor could be the explanation for some parameters of the development, but nobody would have dared to forecast that the Soviet Union would become so occupied with her internal problems that she had no capacity for intervention abroad.

The most complex explanation for the regime breakdown is the loss of legitimacy. In Socialist countries legitimacy could not be measured by surveys. The mass media in the West, such as Radio Free Europe/Radio Liberty, tried to measure legitimacy through the instrument of mail from the East, but results were unreliable. In the early 1980s, it was calculated that the Communists in free elections would not get more than 3 to 5% of the votes, whereas they actually received 10 to 15% in the most developed regimes and much more in the less-developed Communist regimes in the Southeastern parts of Europe.

Was Socialism ever legitimate? Its foundation by force was not forgotten by large parts of the population in the satellite countries. Acceptance of the regime was concentrated in the cadres. With growing success and material benefits, however, legitimacy grew also under Communist conditions.

Paradoxically, Communism collapsed due to its partial success, especially in the sphere of producing intellectually trained elites. There was a mobilization for education, which hardly had an equivalent in the Western world. Communist systems produced a surplus of elites, whom they were unable to funnel into meaningful positions. Western democracies do the same, as periodical overproduction of elites seems to be as inevitable as the famous pig cycle that causes economic slumps in economic and political conflicts. Western systems, however, can offer jobs for new elites in the third 'service' sector when they cannot be integrated into the bureaucracy. This tertiary sector was chronically underdeveloped in Socialist systems. Only the systems that were able to co-opt the dissatisfied young elites, such as Hungary, experienced a slow transition to the new regime. Here the rebellion could be dubbed 'the revolution of the deputy heads of administrative units'.

It would not be 'historical' to look for a single legitimacy for the whole life span of Socialism. Legitimacy also has ideological foundations, and beliefs in legitimation are subject to change. In the early days of revolutionary socialism, the system claimed a kind of teleological legitimation because the party pretended to know the outcome of history. In the Soviet Union, this was combined with charismatic legitimation in the time of Lenin. As time went on, however, both withered away, charisma as well as the capacity to predict the development of history. Quite frequently, the people experienced false prognoses that undermined their belief in the ideology. As Max Weber predicted, the personal charisma of the leader did not survive the founding father. *Veralltäglichung*, the erosion of charisma, was the necessary consequence. Stalin tried to

substitute for his lack of charisma through organization and ideological leadership in all fields – from literature to biology. But this kind of ersatz legitimation was increasingly built on force. With diminishing capacities in the regime for repression and mobilization, new forms of legitimation had to be found. Communist repression had to be substituted by legal security. In the early days, huge groups of defeatist and subversive elements were discovered. After Stalin, nobody believed in this kind of singling out of groups any more. Only in the 'parasitism' and '*chuliganstvo*,' spheres where the Soviet citizen felt endangered for his own security, was he ready to buy from the Communist propaganda.

Communism failed to establish a certain balance between the four basic principles of legitimization in Western systems. The legal state was violated by arbitrary decisions of special hierarchies in the party, in the security forces, and in the planning administration. The nation-state was increasingly invoked by official propaganda in order to reinforce Socialist ideology. However, the hegemony of the Soviet Union prevented the development of authentic, independent, national states, even if more systems tried to embellish the Socialist dogma in national colors. The democratic state was proclaimed by state propaganda, but in reality, for the citizens it was only manipulated participation without alternatives in the political arena. Certain ultra-democratic requisites such as 'recall' and 'imperative mandate' operated only within the aura of the Party, never because of a free decision of the citizens. Thus, the welfare state was used to legitimize the late Socialist systems. In the early days, communist propaganda thought that a social state was unnecessary, because a socialist state is socially minded per se. But the leveling down of all social differences was no longer accepted by the leadership.

During the years of economic growth, Hungarian Goulash Communism or Polski Fiat Communism developed a certain legitimization of the system, but in the 1980s it became clear that the Communist countries were falling further behind the West. Communication with Western countries grew and contributed to a growing capacity in the people to compare East and West. During the 1980s, the system lost its legitimacy due to the economic crisis of Socialism, which was felt in most of these countries.

Transition studies on a quantitative basis confronted us with the finding that democratization is impossible as long as the power resources of a regime are highly concentrated. This assumption was not correct in the case of the Communist countries. All of them had the power to suppress the opposition and had in the 1980s increased their services in both staff and technological equipment. Paradoxically, some of the Socialist countries, such as the German Democratic Republic (GDR) invested most of their technological innovation in the social control of the population instead of investing it in production. Nevertheless, the system collapsed. The enormous security equipment did not help the system survive – as in the cases of the Chinese Wall, the Limes of the Roman Empire, or France's Maginot line in 1940. Unlike these previous cases, the fabulous equipment was not even applied in the last conflict. The index of power resources of the old regimes proved to be of minor importance in the fourth wave of democratization. On the contrary, the better equipped a communist regime was with repressive capacities, the more radical was the change.

Table 1 Pathways to democracy

	Pragmatic piecemeal engineering	*Ideological innovation*
Control from above	Opening of the communist regime (Romania, Bulgaria)	Innovation of socialism (Perestroika, Yugoslavia)
Pressures from below	Erosion of socialism (Poland, Hungary)	Collapse of socialism and takeover by the opposition (GDR, CSSR)

Three models predominated in the system's change in 1989 (see Table 1):

1. (Table 1). System change through the opening of the old regime was achieved by the old cadres of the second rank who kept control of the transition – Romania and Bulgaria (until 1991), Albania (until 1992), Serbia, Croatia, and most of the Commonwealth of Independent States (CIS) (through the first part of the 1990s).
2. (Table 1). Change by innovation was the characteristic of Gorbachev's Perestroika. This type of change proved to be the most complicated. The disintegration of the Soviet Union and Yugoslavia showed elements of a 'bargained revolution'. Bargaining, however, was done not by functional groups but by territorially old and new governments. In no case did the old federation survive and in no case was a new federation feasible after the collapse of the old regime.
3. (Table 1). The erosion of the regime by corporate bargains between the power center and the opposition in a negotiated revolution, took place in Hungary and Poland. This type of transition involved a low rate of participation from among the people, because the change was negotiated by elites without the participation of the citizen. Many voters apparently did not even realize the importance of the change and the voter turnout stagnated between 50 and 60% (Poland, Hungary).
4. (Table 1). The implosion of the Communist regime (Czechoslovakia, GDR). In this model, the control of the 'ancien regime' was least developed. A new elite took power. Continuity of elites and institutions was lower than in the first path to democracy.

Transition theories – in the tradition of theories about the developments of the 1990s – were most interested in the dichotomy between pact and dictate. This dichotomy was confronted with reform and revolution in a matrix (Karl and Schmitter, 1991).

Democratization and Consolidation of the Peaceful Revolutions

'Transitology' as a new branch of knowledge dealing with the peaceful revolutions since the 1970 and 1980s, originally used a sequence model along the lines of liberalization, democratization, and consolidation. Liberalization only took

place in the context of models of innovation as well as erosion of Socialism. The period of democratization is normally identified with institution-building (constitutional power and secondary institutions, such as parties and interest groups). This process was successful in most Central European countries but hardly in the successor states of the Soviet Union. Consolidation of elite attitudes (the 'only game in town' criterion developed by Juan Linz) and the citizens has been incomplete in most post-Soviet countries, upto the present.

Things are different in Central Europe. All countries that became EU members in 2004 (the Czech Republic, Estonia, Latvia, Lithuania, Hungary, Poland, Slovakia, Slovenia) and 2007 (Bulgaria, Romania) are today listed as democracies. However, we have also witnessed substantial backslides. Most often, they had to do with conflicts that date back to the Socialist era or the transition phase. Typically, nationalist governments use non-Democratic means to attack what they see as corruptive networks of elites with a post-Communist background. This has led to polarized politics in Poland, Hungary, and Romania that hollow out the state of law and/or the freedom of the media. In general, however, all the new EU member states have been consolidated by several free elections that reduced the volatility of votes; and they have avoided violence and reduced the weight of extremist parties by alternating governments that included acceptance of even a comeback of the post-Communists, who turned in many countries to Democratic Socialism (Lithuania 1992; Poland 1993; Hungary 1994). In retrospective, the type of revolution has played a limited role for the path of democratic consolidation. More decisive were historic experience with democracy and geographic proximity to Western Europe and the EU. Therefore, the revolutions of 1989/90 have turned into a subject of contemporary history rather than a continued field of interest in social science.

Abstract

This article examines the terminology, taxonomy, etiology, morphology, and the human cost of revolutions from the Renaissance to the Arab Spring. More specifically, the author explores the historical trajectories of different revolutions including the English Revolution, the American Revolution, the French Revolution, the Russian Revolution, and the Mexican Revolution, as well as the recent revolutionary upheavals in Tunisia, Libya, Egypt, Bahrain, and Syria.

This brief article on the general problems of studying revolutions is divided into six sections. The first section discusses the term 'revolution' as an historical phenomenon that has changed its meaning over time with important consequences. The next section discusses the issue of taxonomy or classification, attempting to exclude upheavals that are not really revolutionary, and to distinguish different types of genuine revolutions. The subsequent section discusses the etiology or origins, examining the attempts of historians, political scientists, and sociologists to find common causes of revolution. The next section discusses the morphology or the possibility of finding a paradigm. This section also discusses the problems of drawing a left-to-right graph that has validity for all the great revolutions of modern times and questions the appropriateness of trying to place the course of major revolutions on a grid showing extreme right, right, center, left, and extreme left. The following section discusses the cost of revolutions in terms of human lives. The final section comprises some concluding remarks.

The Evolution of the Term Revolution

Only a handful of historians and social scientists have paid much attention to the history of the term 'revolution,' despite the fact that this history casts light on important developments since the Renaissance. The term emerged from an obscure Latin word meaning the periodic return of a moving object to its point of origin. Throughout the Middle Ages, it was used in its Latin, French, and English forms to describe the supposed cyclical movement of celestial bodies around the Earth. Then it was popularized by heliocentrics following Copernicus's *On the Revolution of the Heavenly Orbs* in 1543. Galileo and his followers used the term repeatedly. Contemporary dictionaries reflected the domination of the term by scientists. In his famous French–English dictionary published in 1611, Randle Cotgrave defined the word as "a full compassing; rounding, turning back to its first place, or point, th'accomplishing of a circular course." Significantly, he gave no nonscientific meanings.

Gradually the meaning of the term began to expand. Poets and playwrights had already begun to appropriate the word. In *The Compleynt of Mars* (1.03), written *c.*1378, Chaucer speaks of 'hevenish revolucioun.' Later, in the beginning of the seventeenth century, Shakespeare preempted the word to describe his view of death. In *Hamlet*, when the grave-digging clown unearths a skull, the prince of Denmark reflects that it might have belonged to a politician, a courtier, or a lord: "here's a fine revolution, an we had the trick to see't (vol. 1)." Shakespeare, thus, used the word to mean the return to one's original condition, earth to earth, ashes to ashes, dust to dust.

While literary men were using the term 'revolution' to mean a cycle, political commentators were already using it to mean a political upheaval. Several Italian authors used the word during the Renaissance to describe political turns of fortune, the replacement of one prince by another, in the city-states of Italy. Then, in 1674, Alessandro Giraffi published a book entitled *Le Rivolutioni di Napoli* to describe the rebellion of the Neapolitans against the Spanish viceroy. Another Italian and a Frenchman used the term to describe the same event. Moreover, Giraffi's book was translated into English within a few years.

In the United Kingdom, most writers referred to the struggle in the middle of the seventeenth century between parliament and the king as the Great Rebellion, but some authors on both sides referred to it as a revolution, for instance the radical parliamentarian Anthony Ascham and the royalist Matthew Wren. In a letter to the Earl of Dorset in January 1646, the royal historiographer James Howell used the word to mean both a political upheaval and the cycle of the years: "for within these 12 years there have been the strangest revolutions and the horridist things happen'd not only in Europe, but all the World Over, that have befallen mankind, I dare say since Adam fell, in so short a revolution in time" (James Hollowell, 1890; *Epistolae Ho-elianae*, Bk. III, 512). His contemporary John Milton also used the word in these two senses (*Paradise Lost*, II, Lines 597–603; VIII, Lines 15–31).

Although the radical parliamentarians in mid-seventeenth-century England claimed that they were restoring ancient rights, they already had some inkling of a new beginning. After the overthrow of the monarchy they spoke of Year I of Liberty, Year II, Year III, and so on for a few years. Some radicals even had a vision of society completely transformed. "But why may we not have our Heaven here," Gerrard Winstanley asked, "and Heaven thereafter to?" (Sabine, 1941: p. 409). Nevertheless, the idea of reversion persisted: even Winstanley was thinking of a return to a primitive simplicity. The royalists also used the word to mean a return to a previous state. For William Temple the return of the Stuart dynasty in 1660 and the Orange dynasty in the Netherlands in 1672 were revolutionary events in the cyclical sense of the word. Although in the second of his *Two*

Treatises on Government, published in 1690, Locke defended the right to revolution, he used the word only twice, each time to mean a return via the state of nature to a previously existing constitutional position (1964, Cambridge edn. paragraphs 223 and 225, 432–433).

Oddly enough it was not the Great Rebellion of mid-seventeenth-century England which made the word an important term in political vocabulary. Only after the Glorious Revolution in 1688 did lexicographers assign the word a political meaning. The use of the word to describe the overthrow of James II and the signing of the Bill of Rights by William and Mary gave the word a wider meaning. It was not quite a restoration of a previously existing order, rather it consolidated and advanced rights for which parliament had fought for the preceding century. Nevertheless, it was a very conservative event, entrenching the power in the parliament of aristocrats, landed gentry, and rich merchants. Also, the Revolution was not seen as something with a universal application; it was viewed as English, unique, and unrepeatable. The Bill of Rights of 1688 was not for all humanity.

Then in the last quarter of the eighteenth century the term came to mean a profound rupture with the past and the beginning of a new era. On the Great Seal of the United States, we see 1776 associated with the Latin motto *Novus Ordo Seclorum*, 'a new order in the ages.' Then the French Revolution consolidated and intensified the idea of a new beginning in history. Like the Commonwealth-men earlier, they renumbered the years starting in 1789. When the Republic was established in 1792 they began to number the years Year 1 of the Republic and so on. Finally, in October 1793 the Convention introduced a new calendar numbering the years, not from the birth of Christ, but from the inauguration of the Republic on September 22 of the previous year. Even more significant was the fact that the French revolutionaries believed that their ideals would have a universal appeal. The three Declarations of Rights – 1789, 1793, and 1795 – were to apply to all men, not just Frenchmen.

Because of the cluster of revolutions in the late eighteenth and early nineteenth centuries, revolution became recognized as a recurrent phenomenon. This in turn led to the appearance of a new character on the world stage: the professional revolutionary. There was an apostolic succession of such characters – Filippo Buonarroti (1761–1837), Auguste Blanqui (1805–81), Mikhail Bakunin (1814–67), Piotr Kropotkin (1842–1921), Victor Serge (1891–1947), Sun Yat-sen (1866–1925), Mao Zedong (1893–1976), and many others. These life-long revolutionaries anticipated revolution, created organizations to bring it about, and formulated plans about what to do when it arrived. Thus, were born the revolutionary political parties which changed the course of modern revolutions. Once such parties capture power, they are able to suppress opposition for very long periods. Until these parties are finally dislodged from power changes in policy can only take place by decisions within the party leadership.

Taxonomy

Many upheavals are labeled revolutions, but few actually qualify for the term. Most *coups d'état* do not qualify since participation in them is limited, and their result is often confined to a change in government personnel. So-called 'palace revolutions' usually involve struggles with factions or families within the government. Rebellions should probably be excluded, not only because they do not succeed, but also because they usually lack a clear program and are often led by nobles who do not really want to destroy the existing political and social order. Even wars of independence are dubious candidates for the term, contrary to conventional usage. Even the American Revolution scarcely deserves this title. Although the War for Independence saw individual rights entrenched, considerable exchange of property, and a large emigration, the internal institutions of the new states were not radically different from those of the former colonies. Some African struggles in the twentieth century against European imperialist powers had arguably deeper internal repercussions.

Even among upheavals that deserve the title there are many degrees of revolution. There are political revolutions such as the Revolution of 1830 in France, which produce a change in the groups enjoying power, but do not shake society up very much. The great vertical upheavals or social revolutions such as the French Revolutions of 1789, the Russian Revolution of 1917, or the Chinese Communist Revolution of 1949, have led to deep social changes. The latter two, however, are not only political and social revolutions, but socialist ones as well. The Babouvist Conspiracy of Equals in France in 1796 was probably the first case of a group, in which some members supported a primitive communist ideal, which actually tried to seize power. Genuine socialist revolutions, attempting to control and redirect the means of production, could obviously not occur until socialism developed in the nineteenth and twentieth centuries.

Revolution in the deepest sense involves not only a change in the groups exercising power, profound changes in the social structure, and in modern times an attempt to change the control over the means of production, but also an attempt to change the way citizens think, feel, and act. There are glimmerings of such an attempt in the Hussite and Puritan Revolutions, but the French Revolution of 1789–99 was the first to try to implement it in a large way. At the peak of the Revolution in Year II the *gouvernement révolutionnaire* tried to 'regenerate' citizens through an attempted mobilization of all the existing media: art, architecture, festivals, music, newspapers, theater, and children's books and games. Such use of the media has since become a feature of major revolutions on both the left and right, such as Nazi Germany, Bolshevik Russia, and Communist China. Comparative studies of revolutions seldom discuss this added dimension to revolution.

Etiology

There has been great attention to the question of the origins of revolution. If it were possible to establish common causes for revolutions, it would greatly simplify the study of the great revolutions since the seventeenth century, each of which has produced thousands of studies. Once common causes were identified, this knowledge would also be useful both to those anxious to promote revolutions and those intent on preventing them. The hope of applying social science for such purposes

has produced such books as Michael Velli's *Manual for Revolutionary Leaders* published in 1972, and on the other side the collection edited by Harry Eckstein (1963), intent on curbing such internal violence.

Since Aristotle, there has been wide discussion of the etiology of upheavals, rebellions, and revolutions. Most historians, however, do not find the literature comparing revolutions of much use in understanding the revolutions in which they specialize. Many of them point to the problem of assessing the weight to be given to various factors at work, before and during revolutions. Unlike scientists who can run experiments in which all factors except one are held constant, historians cannot rerun events to test the role of certain factors. An historian, for example, cannot demonstrate precisely how the closing decades of the eighteenth century in France would have been different if reformers had been able to solve the financial problems, if those problems had not been exacerbated by intervention in the American War for Independence, if there had been a different King from Louis XVI, if he had not called royal troops into Paris in July 1789, if he had not tried to flee the country in June 1791, if the Girondins had not led the country into war in 1792, or if Robespierre had never been born. Similar questions can be posed about all subsequent revolutions. Specialists try to weigh various factors by getting as deeply as possible into the complexities of each upheaval.

Aristotle argued that rival concepts of justice led to upheaval. Modern theoreticians such as Karl Marx, Max Weber, Pitirim Sorokin, Lyford Edwards, Jaroslav Krejci, Mark Hagopian, Peter Calvert, Chalmers Johnson, and a host of others have focused on increasing tensions in societies leading to revolutions, provided there are precipitants and triggers. These tensions are described in various ways including class conflicts, other contradictions of various kinds, frustration of the expectations of certain groups, dissynchronization between social development and existing values, and other sources of disequilibrium. The fact that there have to be severe tensions in society in order to have an internal war seems a truism. The difficulty with such generalizations is in applying them to very different circumstances. Take, for example, the varying role of war. The American Revolution was made possible in part because the threat of invasion from French territories to the north had been removed by the British victory in the Seven Years War. France was not at war when the revolution broke out in 1789. In contrast, the government in Russia had been severely undermined by war by 1917. Also in China the long struggle with Japan contributed to the collapse of the Guomindang and to the Communist victory in 1949.

Another important variation among revolutions is their very different objectives. As was mentioned earlier, there were no socialist revolutions before the twentieth century. Twentieth-century revolutions in Russia, China, Cuba, and elsewhere have attempted to seize and redirect the means of production. Related to this has been the attempt of countries such as Russia, China, and North Korea to force development in order to catch up with Western Europe and North America. Such a drive was not present in the Hussite, English, or French Revolutions; in fact the hope for a sudden increase in productivity could scarcely have arisen before industrialization, steam power, electrification, and the introduction of internal combustion engine. Comparing revolutions over five or six centuries seems to minimize new ideologies, in fact novelty in human history.

One way of looking at the objectives of various revolutions is to study how they were symbolized. In the French Revolution, the dominant symbols were the figure of Liberty, which gradually evolved into the figure of the Republic, the Liberty Bonnet, and the Liberty Tree, none of which reappeared in the Bolshevik Revolution. Russian revolutionary symbolism featured giant figures of workers holding Hammers and Sickles, workers depicted as part of industrial machinery, electric lights in modernized villages, and of course red stars and flags. In Maoist China there were no symbols of liberty, but thousands of images of Mao like a red sun in the sky, numberless little red books of Mao's writings, and endless images of peasants using muscular power to create terraced hillsides, build dams, canalize rivers, and irrigate the lands. In fact, their terraced hillsides became a symbol of using intensive labor to 'conquer nature.' Machinery was relatively inconspicuous until after Mao's death in 1976. The figure of Liberty was absent until students made her prominent briefly in the abortive democracy movement of 1989. Comparative studies of revolution have so far largely ignored different allegorical figures and symbols.

Morphology

There are similar problems with the attempt to find common patterns in the course of revolutions. One of these is that most historians, sociologists, and political scientists give much more attention to the origins of revolutions than to the inner dynamics that drive them forward, producing the curves so dear to social scientists. A further problem is for how long a period one considers a curve. Jaroslav Krejci extends the Hussite Revolution over 50 years, the English Revolution over 60 years, and the French Revolution over 100 years. Can one speak of a single French Revolution over a century which saw two empires, three forms of monarchy, five revolutions (if one considers 1792 a revolution within the revolution of 1789–99), and numerous coups? Also, if you compare his graphs of the six revolutions that he covers – the Hussite, the English, the French, the Russian Bolshevik, the Turkish, and the Chinese Communist Revolutions they vary considerably from each other (1983: pp. 35, 67, 82, 117, 149). Moreover, his curves vary considerably from those published by Mark Hagopian (1974: p. 245). Also, it is strange that Hagopian shows the Chinese Revolution dipping in 1958, the precise date of the Great Leap Forward. Obviously, reducing great revolutions to scientific-looking graphs is a risky endeavor.

A further problem arises from placing revolutions on a grid marked extreme right, right, left, and extreme left. These terms arose from the accidental seating of conservative deputies to the right of the speaker in the Constituent Assembly in the French Revolution of 1789. In the liberal democratic revolutions in Europe and North America the left has usually meant those who supported genuine parliamentary government, political opposition, and defense of human rights. Can one, however, put the English, the American, and the French Revolutions on the same right–left grid as the Russian, Chinese, and Cuban Revolutions? Placing modern communist revolutions on the left distorts the original meaning of the term. These

twentieth-century revolutions have introduced single-party regimes, have created assemblies that approve decisions already made by the leaders, and have violated human rights. In fact, the way they have operated is very similar to governments on the extreme right, *'les extrêmes qui se touchent,'* as the French put it. This is another example of the perils of applying the same grid to revolutions with very different objectives and consequences.

If the etiology and morphology of revolutions were clear, we should have been able to predict the upheavals in Tunisia, Libya, Egypt, Bahrain, and Syria in 2011–12 and their likely outcomes. Social scientists should be very modest, however, because very few of us predicted these uprisings. At the same time, all the literature on pattern in revolution does not enable us to predict with any certainty the outcome of any of these insurgencies. The metaphor used by western journalists, 'the Arab Spring,' may prove to be completely misleading. In all these countries, the Islamic parties that have been held in check by authoritarian governments, appear ready to move into the vacuum left by the expulsion or liquidation of leaders such as Ben Ali in Tunisia, Muanamar Gaddafi in Libya, and Hosni Mubarak in Egypt.

The future of the unrest in Bahrain is uncertain because already Saudi tanks have rolled over the causeway linking it to Saudi Arabia to support a fellow Sunni ruler, Hamad al-Khalifa, against a Shia majority. Further, the outcome of the bloody uprising against Bashir Al-Assad and his Alawite supporters in Syria remains uncertain. If Assad eventually falls, the Saudi Arabians would prefer the Sunnis to take over, which would not be in the interests of the Shias and Christians who have enjoyed a degree of toleration. John R. Bradley, one journalist who *did* not predict revolution in Egypt, warns in *After the Arab Spring*, Palgrave, 2012, that these uprisings may be the prelude, not to liberal democracy, but to the rule of radical Islamists.

The Cost of Revolution in Human Lives

In the comparative study of revolutions scant attention has been given to their cost in human lives. Whatever benefits revolutions bring, these have to be balanced against their toll in human suffering and death. Calculating this cost is difficult because many revolutions involve civil war and international conflict, plus the question of whether or not to include famines that may have been precipitated by political actions. There is, however, a clear trend: as revolutions have moved from being primarily political upheavals to great social upheavals their toll in human lives has mounted dramatically. The English Civil War 1642–46 between the Puritans in parliament and the High-Church supporters of Charles I, which many historians label a revolution, saw the death of about 190 000 Englishmen, including in the end the king himself in 1649. This upheaval culminated in the Protectorate of Oliver Cromwell who ruled the country until his death in 1658. His invasion of Ireland, where the Catholics were predominantly royalist, resulted in around 400 000 deaths.

The American Revolution, which as we have seen led to an expansion of the meaning of the term revolution, was principally a struggle against English imperial control. Most of its victims died in this war, about 25 000 American servicemen out of around 200 000 who were under arms at one time or the other. No one was executed because of his or her loyalty to George III, although a few died in the aftermath of tarring and feathering, and some were executed as suspected spies. The French Revolution, 1789–99, saw many more deaths. These victims are engraved in our memories because of the images that have come down to us of the condemned being transported in tumbrils to the guillotine. Overall about 40 000 were executed or died in prison, while around 250 000 died in the suppression of counterrevolutionary revolts within France. Then the revolutionary wars against much of Europe in 1792–99 evolved into the Napoleonic wars lasting until 1815 in which about 3 000 000 soldiers and around 1 000 000 civilians died.

The Mexican Revolution, roughly a war between large landowners on one side and small ranchers, unemployed cowboys, and landless peasants on the other, lasted from 1910 till 1920 and cost about 2 000 000 lives. The bloodshed in the Russian Revolution of 1917 resulted in around 1 000 000 military deaths, about 5 000 000 who died in famines, around 2 000 000 victims of disease, plus more deaths by terror or crossfire. By 1928, Joseph Stalin had seized power, retaining it until his death in 1953. His ruthless rule led to about 20 000 000 deaths including liquidation of the Kulaks, purges of possible rivals, prosecution of alleged counterrevolutionaries, famines induced by political policies, and atrocities during the Second World War. These infamous events have been immortalized in literature by authors such as Alexander Solzhenitsyn, *The Gulag Archipelago*, published in the West in 1973.

Modern China, however, breaks the record for revolutionary deaths in modern times. The Taiping Rebellion, which lasted for 14 years, 1850–64, and covered an area the size of western Europe, never was awarded the title of 'revolution' despite costing about 20 000 000 lives, probably because it never succeeded in overthrowing the Qing dynasty. The Communist Revolution in China was arguably the bloodiest upheaval in history. The Communist struggle for power against the Nationalists cost around 7 000 000 lives, 5 000 000 in the first phase, 1926–37, another 2 000 000 in the second phase, 1945–49, not including the 10 000 000 killed in the war with the Japanese. Then the regime led by Mao Zedong from establishment of the People's Republic in 1949 until his death in 1976, was arguably the bloodiest in history. This bloodshed was the result of Mao's effort to purge the privileged members of the old order and then periodically to push the revolution forward – the liquidation of landlords during the Agrarian Reform 1950–51; the Three-Antis campaign 1951–53; the Five-Antis campaign 1952–53 (they overlapped); the Anti-Rightist campaign in 1957, which followed the 100 Flowers Movement encouraging intellectuals to criticize the Party; the Great Leap Forward 1958–62, which led to a disastrous famine; and the Great Proletarian Cultural Revolution 1966–76. Experts differ in estimating the number of victims of these spasmodic purges and lurches forward. The Walker report to the US Congress in 1971 estimated that some 32 to 59.5 million people were killed. Stephane Cortois et al. (The Black Book of Communism, Harvard, 1999) estimated 65 million deaths under Mao (Jung Chang and John Holliday, Mao: The Unknown Story, Knopf, 2005), set the total at 70 million. Only when the Chinese archives are opened will we have firmer

figures, but there is no doubt they will be high, probably at least 40 million.

Conclusion

While it seems very difficult to establish a common taxonomy, etiology, and morphology covering all the major revolutions in the past five centuries, this does not mean that the comparative study of revolutions is not worthwhile. The history of the term 'revolution' demonstrates that it has taken on important new dimensions since it first became politicized in Renaissance Italy. The taxonomy of revolutions can exclude upheavals that are not full revolutions and can distinguish among political, social, and socialist revolutions, or combinations of all three. The etiology of revolutions is particularly problematic because the conditions that occur vary widely; nevertheless the idea that disequilibrium of some kind precedes revolution seems a valuable one. In many cases revolutions occur when society is changing while the regime stands still, but in the case of the Iranian Revolution of 1979 the reverse seems true – disequilibrium resulting from a westernizing Shah moving more quickly than powerful conservative groups, especially religious ones, were willing to accept. On the other hand, the collapse of the satellite Communist regimes in eastern Europe after 1989 seems to be the result of the failure of those governments to satisfy the needs of their citizens and the weakness of systems imposed by external force. As for establishing a common pattern or morphology, the differences in the graphs that scholars have produced warn of the dangers in such attempts. Those historians, however, who steep themselves in just one revolution, are very unlikely to recognize what is unique about the particular upheaval in which they specialize.

Since revolution has been a recurrent phenomenon, and may be so in the future, social scientists will doubtlessly attempt to reach general conclusions about them. In such future attempts more attention needs to be given to the internal dynamics of revolutions once they have broken out. The idea of attempting to create a new citizenry by mobilizing all the available media, which has marked revolutions since 1789, deserves further study. So too does the use of symbols, allegorical figures, and political images that have distinguished revolutions in modern times. Moreover, graphs based on a left-to-right scale need to be modified since the meaning of left and right has shifted drastically over time. Finally, the comparison of revolutions must bring out the unique dimensions of each revolution instead of focusing mainly on similarities.

Abstract

The modern concept of revolution comes out of one particular experience at the end of the eighteenth century, an experience that led some to hope for and others to fear similar occurrences. Reflections on the nature, causes, unfolding, and consequences of revolution were for a long time dominated by the French Revolution. As other cases came to preoccupy social scientists, particularly in the wake of the varied social upheavals of the late twentieth century, scholarly reflection on revolution flourished as it developed in new directions. These included greater attention to culture, more emphasis on contingency and agency, and incorporation of ideas from the study of social movements. In the early twenty-first century, new social movements were again getting scholars to rethink not just their approaches to the study of revolution, but to reconsider what forms revolutions might take.

An Old Word Takes on a New Meaning

'Revolution' (from Latin *revolutio*) initially had the sense of a return to a point of origin. In political discussion, it might be used to characterize a dynastic restoration. By the seventeenth century, it had also taken on the sense of an alteration in fortune and might be employed to describe some significant improvement or deterioration in political affairs. In this latter sense, revolutions were often seen as frequent occurrences. One sees this double set of meanings in later reflections on dramatic seventeenth-century events. Beginning in the 1640s, conflict between England's king and parliament led to civil war, the king's execution, widespread social upheaval during which movements championed radical causes, and new forms of government. For some eighteenth-century writers, the installation of a new monarch in England in 1688 was a great singular revolution in the older sense of a return to an initial state of order after several tumultuous decades; for others, it was but one of the many revolutions – in the sense of another dramatic turn of political fortune – that had marked all of English history (Rey, 1989).

A century after this 'Glorious Revolution' in England, the geographic range and social diversity of French turbulence in 1789 and beyond (rural and urban insurrections throughout the country; military mutinies; elite challenges to royal authority; priests defying bishops; a tidal wave of legislative enactments) provided many revolutions (in the plural) for commentators to reflect upon. But, as these upheavals continued to multiply and as various contenders sought to channel the dramatic events in one or another direction, participants began to speak of these many separate events as components of something singular, the French Revolution, that had a structure and causes, that was an ongoing process, and that rival contenders sought to understand and control. Some participants who were disappointed by specific events in France could even imagine that this particular process was but one instance of possible revolutions and could look forward, as one radical group declared in 1794, to "another, far greater, far more solemn revolution" of which "the French Revolution is but the forerunner" (Furet and Ozouf, 1988: 203). So some sought to make new (and perhaps differently constituted) revolutions and others to avert them; and theorists of either (or neither) persuasion sought to understand them.

Until 1917, the French instance was the central source of empirical evidence of what a revolution might be like. Since the French Revolution inspired some to work for that revolution of the future, either to replicate or to improve upon that model, one of the sources for thinking about the causes and consequences of revolution came from those engaged in trying to bring them about. But others, hoping they could be prevented, also sought to understand their deep causes and their immediate precipitants. Much nineteenth-century reflection on the potential for collective action of the new industrial working classes and the expanded urban populations of Europe and North America – one of the wellsprings of the emerging discipline of Sociology – was precipitated by fears and hopes surrounding revolution.

Much sociological reflection was profoundly stimulated by spectacular failures of radical causes to seize and hold power, despite episodes of impressive popular mobilization such as the widespread European turbulence of 1848, the Paris Commune of 1871, or the Russian upheaval of 1905. But theorists were paying relatively little attention to social conflicts in lesser powers or far from Europe. Even well into the twentieth century, other revolutions, both imagined and experienced, were apt to be understood with concepts derived from the French experience. Military terminations of popular upheaval were held to be 'Bonapartist'; Russian revolutionaries accused each other of being 'Thermidorians'; it has remained very difficult to think of political conflict without invoking notions of 'left' and 'right' (initially, spatial locations in revolutionary France's legislature).

The Russian Revolution of 1917 added some new possibilities to stimulate imaginations. Attention turned to the role of revolutionary parties as organizers of mass discontent or fomenters of it, as refiners of popular grievances, or as carriers of visionary ideologies not necessarily aligned with mass concerns. The formation of a transnational revolutionary organization, the Comintern, brought to the fore a host of questions about the interplay of national and global processes. The revolutionary seizure of power by a party claiming roots in Marxism raised important sociological questions. Marx had

analyzed the material circumstances within which social classes were formed and acted. He argued that the modern industrial working class was to be the prime mover of the future. But Bolshevik success in 1917 could hardly be reduced to the actions of the 'working class.' Nor did it seem possible to account for their triumph as the automatic playing out of environing material circumstances without considering their ideas as revolutionaries and their improvised tactics (Haimson, 1955; Rabinowitch, 1976). A debate about determinism and voluntarism had long preoccupied Marxists, one that has echoes in early twenty-first century preoccupations of scholars of revolution with 'structure' and 'agency.'

Academic scholarship on revolution commonly focused on France and Russia and a small number of other, the so-called 'great,' revolutions and sought to discern their common processes or causes, more rarely their outcomes. In an influential treatment, historian Crane Brinton (1938) sought out the common causes of four revolutions and then developed empirical generalizations about commonalities in their unfolding, arguing, for examples, that 'moderates' are superseded by 'radicals,' but that radicalization eventually generates a 'Thermidorian reaction,' as part of a 'natural history' of revolution. This approach was superseded by sociologists who sought more theoretically grounded accounts of structures, which nurtured revolution. Skocpol (1979) sought the commonalities and differences among three cases and held that a combination of class-based revolt from below, particularly in the countryside, and a state unable to raise needed resources was explosive. State incapacity was explained as the inability to raise the resources demanded by interstate military competition or actual warfare, particularly when state initiatives were stymied by the successful opposition of dominant strata. Different as their specific theses are (Brinton pays little attention to the countryside and a lot to revolutionary ideologies, emphases reversed in Skocpol) they both take up the essential instances of France and Russia, on everyone's short list of revolutions.

But the post-World War II era, with its many anticolonial struggles, civil wars in which at least one party has claimed itself to be revolutionary, and regime transitions of many sorts, has provided even more food for thought about the causes, dynamics, and consequences of revolution and suggested new approaches (Goldstone, 2009). By the early twenty-first century, the French dramas from 1789 onward no longer stood as the central model for theoretical contemplation.

Revolutions in China, Vietnam, or Central America clearly seemed to have as much to do with structures of global domination as they did with the national particularities of social relations. Scholarly attention was soon directed toward a wider canvas. This is not only because those instances from the second half of the twentieth century were far from Europe, but also because some of those instances involved revolutionaries who hoped to challenge the world order, not just the locally dominant strata. They also suggested that there was a history of revolution, not just a history of particular revolutions, as revolutionaries adapted lessons learned from previous episodes to the current moment. Revolutionaries on a now geographically expanded stage claimed to be the legatees of a contested tradition that led from France to Russia, then to China, and then to quite a variety of other places.

But the Iranian Revolution that began with the fall of the Shah in 1979 was hard to situate within this particular historical story since its leaders claimed a different heritage. Theoretically, the Iranian events stimulated reflection on the cultural aspects of revolution, on the ways in which revolutionaries understood themselves, and their role in advancing toward a more desired future state of affairs. The rapid overthrow of the Soviet-style regimes of Eastern Europe and then the Soviet Union itself starting in 1989 raised even more questions, since the oppositional leaderships and those who ascended to power did not claim to be the heirs of an alternate revolutionary tradition and sometimes did claim to be rejecting the idea of revolution altogether. If the later-twentieth century might be called the true 'age of revolution' (Goodwin, 2001: 3), it also ushered in new scholarly emphases.

An Elusive Definition

Despite two centuries of reflection and an extremely vigorous body of comparative scholarship on revolution since the last quarter of the twentieth century, the very definition remained in dispute. First of all, to the extent that notions of revolution were abstracted from that singular French experience rather than from some sense of the commonalties of a large number of experiences, observers could readily differ on what they thought were defining features. Some of the elements that, in varying combinations, entered into various definitions might include:

- Illegal seizure of national political power.
- Extensive property transfers.
- Radical alteration in the form of government.
- Pervasive change in a wide variety of institutions.
- Extensiveness of popular mobilizations.
- Resistance to change by the previously privileged.
- Substantial violence.
- New formulas for the legitimation of authority.
- A new elite's claim to be effecting a radical break in the course of history.
- A new elite's claim to be advancing forward to a new level of human progress.
- Widespread sense of profound change, including at the centers of national power, in local arenas, and reaching into daily life.
- The development of new civic rituals and new ways of justifying rule.

This definitional debate opened up a whole host of fruitful questions about how these phenomena might be connected to one another.

Like many other concepts used by political actors, the term revolution has continued to be a term of legitimation and delegitimation rather than simply analysis. All sorts of things have been labeled (or not labeled) as revolutions in order to honor (or dishonor) them. This has been terribly confusing. A grammatically simple sentence, 'Revolutions entail considerable violence' might be any of at least four very different sorts of statement: part of a *definition* of revolution; a *proposition* about revolution (when defined without reference to violence); an *exhortation* to violent tactics (when uttered among

committed revolutionaries); or a *condemnation* of revolution (when uttered among people who abhor violence).

One reason such debates about defining conditions were ongoing was that they were abstracted from a small number of cases, raising theoretical questions about which subset of conditions would be necessary to qualify another event as a proper revolution. The various armed insurgencies of Southeast Asia, Africa, and Latin America, whether successful, stalemated, or defeated did not reframe the issues. But the serial regime overthrows in the European communist zone were conceptually challenging. They involved deep changes in the formulas of political legitimation, ushered in new forms of political life, reconfigured international relationships, and saw enormous transfers of property. But in 1989, apart from Romania, nonviolent mobilizations and negotiated rather than resisted transitions were the norm. They also lacked the vision of a world-transforming, new social order that would set history on a different course. The East German mobilizations of 1989 aroused great scholarly interest for their combination of rapid expansion to enormous numbers of participants and very little organizational infrastructure (Opp et al., 1995; Hirschman, 1993). Many of the new leaderships took as models of economy and polity the capitalist democracies of the West and mounted no ideological challenge to transnational structures of domination with the result that they were supported rather than opposed by wealthy and powerful states. Some would, therefore, not judge them instances of revolution.

But other scholars have suggested that a new model of revolution was, at hand, largely characterized by mass mobilizations of an overwhelmingly nonviolent character accompanied by negotiated transitional arrangements and urge us to engage in 'redefining revolution' (Garton Ash, 2009: 375) or understand the specific processes of 'nonviolent revolutions' (Nepstad, 2011). Scholars soon noted that possibly relevant instances of this apparently new model were far more numerous than the events of 1989 itself and had happened earlier. There was the Philippine termination of the Marcos regime in 1986 and the even earlier Portuguese 'Revolution of the Carnations' of 1974, for example. Indeed, new scholarship strongly indicates that mass nonviolent protest has been more successful in impelling a political transition than has violent opposition since at least the early twentieth century (Chenoweth and Stephan, 2011).

All of this suggested to some scholars a radical rethinking of the subject matter, away from the conception of revolution as the rare successful, violent struggle to set history on a new course to returning to something like the pre-1789 conception of a radical change in political fortunes that happens with some frequency (Goldstone, 2009). If these are not everyday occurrences, revolutions thus understood, in Tilly's (1995) enumeration, have happened hundreds of times in Europe alone.

Major Research Traditions

Divergent emphases fueled overlapping but distinguishable traditions of research on popular collective mobilization, regime overthrow, political violence, elite dissidence, governmental legitimation and delegitimation, institutional change, and class conflict, and a good deal of reflection on how such processes affected each other. Beginning in the nineteenth century, a well developed Marxist tradition examined ways in which long-term economic transformations created new group identities and interests, while altering political structures. Revolution was seen as a traumatic readjustment of power relations, at bottom, driven by the shifting economic interests of rational actors (Marx and Engels, 1955[1848]; McLellan, 2007). In an important variant, capitalism was seen as generating profoundly destabilizing cyclical economic crises. Economic historian Camille-Ernest Labrousse (1944) argued that cyclical food crises were triggers of major insurrectionary events in the past, including the French Revolution, and other writers, from Marx on, argued that industrial capitalism from the nineteenth century on cyclically generates vast misery. The important theoretical issues for scholars in this tradition were how to connect this mass suffering with the popular insurrection it only sometimes triggered, and where and when it did so to connect that insurrection with the specific programs and tactics of revolutionaries. One important element sustaining this approach to the problem was that it was a theme for continual debate among revolutionaries themselves, especially those who identified with one or another Marxist variant. As scholars come to pay attention to global contexts, some began to consider the geographic aspects of cyclical processes as well and examined how forms of conflict moved in space as well as time (Silver, 2003).

A theoretically more diffuse body of work looked for strains of various sorts produced by industrialization, urbanization, and secularization and tried to explain collective outbursts as responses to such strains. In such interpretations, revolutions were apt to be seen as 'moments of madness,' as frenzied and doomed responses to the forces of modernity, for example, in Durkheimian notions of 'breakdown' or in the 'collective behavior' research tradition (Durkheim 1966[1897]; Smelser (1962)). This approach made revolutions a by-product of 'modernization.'

Tocqueville's thesis linked the growing might of a rationalizing state with a broad array of cultural transformations that undermined the legitimation of aristocratic privilege by transferring to the state activities previously carried out by the lords; indeed, the lords might themselves become oriented to serving the new state bureaucracy. As states did more and lords did less, aristocratic privilege was no longer experienced as a by-product of public service but as theft and oppression. This attack on the problem lay relatively undeveloped in twentieth-century social science until revived by a renewed sociological emphasis on the state from about the 1970s, when sociologists like Theda Skocpol (1979) and Jack Goldstone (1991) saw both the growing reach of states over historical time and moments of seriously diminished state capacities as key sources of revolutionary processes.

The Post-World War II Era

The social upheavals of the post-World War II era brought many new instances of collective action, political violence, and regime overthrow into play. Anticolonial movements, some defeating great powers (as in Vietnam), long-term rural warfare with divergent outcomes (as in Guatemala and Nicaragua), and

Third World state breakdowns (some leading to radically new regimes, as in Iran), all added new cases.

The vastness of human suffering so evident in the twentieth century increasingly suggested attention to opportunity and resources, as well as grievance in the genesis of revolt and the success of revolution. Since revolt was so much more scarce than misery, it was evident that something other than (or at least in addition to) suffering was needed to explain dramatic struggle for change and social scientists became adept at identifying structures and moments that furnished opportunities and resources, including organizational capacities, that might make mobilization more likely. If one peasant community rather than another supported a revolutionary movement, social scientists now sought an understanding of what resources in the daily lives of these (but not other) peasants might account for why these (but not other) peasants revolted. If one revolutionary party in a small, poor country (for example, Nicaragua) succeeded in coming to power, while another revolutionary party in another small, poor country (for example, El Salvador) succeeded only in sustaining a bitter, stalemated war with the government, social scientists began to explore the differential vulnerabilities of different kinds of regimes. One argument in this tradition held that a more broadly based regime was harder to overthrow than one that essentially served a very narrowly constituted group such as a tyrant's friends and family (Goodwin, 2001; Wickham-Crowley, 1992). Distinguishing long-standing differences in resources available to rebels from temporary opportunities, and distinguishing stable structures of elite domination from specific policies, became very important for this research tradition. A 'structural' school of explaining revolution was emerging.

One very important circumstance that commonly emerged in such accounts was diminished state capacities. Skocpol (1979) argued that state incapacity to raise the resources to deal with a dangerous international environment had multiple ramifications that could interact with sources of mobilization from below. Goldstone (1991) extended this by showing that political upheavals commonly featured the mutually exacerbating combination of three processes: a fiscally strained state struggling ineffectively to raise resources, intraelite conflict, and popular revolt. This was a very general model that could guide research on particular instances by examining the pressures on and capacities of a particular state, the sources of solidarity and division among a particular elite, and the abilities to resist heightened demands upon them of particular popular actors.

But accounts of favorable structures soon seemed incomplete as well. The Iranian Revolution of 1979, in which many leading participants spoke a religious language at radical variance with the language of those who had come to power in previous, paradigmatic cases, brought many scholars to reconsider the role of cultural elements in revolutionary processes. This instance of revolution, moreover, caught the attention of social scientists at a moment when the social sciences were engaging in what many called 'the cultural turn,' which soon informed the sociology of revolution as it had other fields of inquiry. A new group of scholars was stressing the ways in which social movements might frame issues in culturally resonant ways or even forge what John Foran (2005) called "political cultures of opposition." Eric Selbin (2010) has argued that revolution is experienced as participating in a story that connects present struggles with understandings of the pasts from which they spring and the futures toward which they strive. One such story connects one revolution to another as imagined futures are glimpsed in France, reemerge in Russia, picked up in China, then Vietnam and Cuba, and elsewhere. This particular story is disrupted by Iran, which does not fit, and by 1989, which terminates a big part of that narrative in a very different place than anyone dreamed of in 1917.

Many instances in the late twentieth century and beyond were occurring in lesser powers on the world stage, in places obviously subject to military, economic, or ideological domination by more powerful states, and whose upheavals often involved attempts (some partially successful) to throw off some of these forms of domination. One would hardly try to understand anticolonial revolutions without paying attention to the policies and institutions of colonial rule, social upheavals in countries exporting tropical crops without paying attention to the world economy, and the resources available to governments and rebels in small, poor, and weak countries without paying attention to the capacities of both sides to elicit support from great powers.

Insights garnered in examination of the newer instances began to suggest different emphases in new examination of older cases. The French or Russian revolutions were looked at as cultural processes; the embeddedness of the 'great' revolutions of the past in transnational connections was noted; conflicts beyond the few previously paradigmatic instances entered the comparativists' field of vision. Scholars began to explore the French Revolution, for example, in the context of the global struggle among Europe-centered empires for world domination. The very variety of participants in the newer cases expanded the intellectual horizons of researchers. As varying combinations of participants in the newer cases became evident, comparative scholars were recognizing how multisided were the conflicts in past revolutions as well. The view of revolutions as the displacement of the domination of one reasonably clearly defined social class by another, was increasingly replaced by the view that revolutions involved actions by multiple social strata, some perhaps defined by class, and some with other sorts of identities, including nationality, neighborhood, ethnicity, gender, region, religion, and age, not to mention identities like 'activist' and 'revolutionary.'

Revolutions, both past and recent, were increasingly likely to be seen as complex affairs in which governing authority failed in many different ways, elites divided in many different ways, and rebels mobilized in many different ways. Methodologically, this meant that social scientists were likely to be looking at configurations: at complex intersections and interactions of processes that mobilized collective actions of varying kinds, produced elite conflict, and weakened governing institutions. Theoretically, this meant that the search for generalizable statements about necessary or sufficient conditions for revolution needed to be rethought.

Emerging Directions in the Sociology of Revolution

The issues engaging comparative scholars in the early twenty-first century meshed with some of the large issues engaging

macrosociology generally, indeed, were suggesting revolutions as a fertile terrain for engaging those issues. Among the issues generating much discussion:

- *how to integrate cultural accounts with structural ones*: Cultural issues were an emerging agenda in various ways. Social historians were making enormous advances in understanding popular culture in varied times and places. A new generation of scholars was examining the overt cultural politics of revolutionary elites. The direction of change in such places as post-Shah Iran and post-communist Eastern Europe seemed altogether impossible to discuss without considering legitimating ideas. Resistance to oppression was seen as having a significant cultural dimension and revolutionary visions were analyzed as stories (Foran, 2005; Selbin, 2010).
- *how to integrate accounts of individual action with macrostructural processes*: As elsewhere in sociological theory, this at first constituted a major challenge and occasioned much debate. Proceeding from the assumption of individual rational actors, how could one account for the forms assumed by collective action, especially in light of the often evident individual risk assumed in participation in revolutions in combination with their uncertain and often undesired outcomes? Lichbach (1995) has shown that there are a variety of plausible answers.
- *adequate attention to the visions of revolutionary elites, the wellsprings of popular mobilizations, and the interaction of the two*: Some structural accounts seemed to make the visions and intentions of revolutionary leaderships inconsequential; some other accounts seemed to make them everything and by implication ignored the motivations, intentions, and wishes of ordinary participants. Some urged us to consider how it was that some revolutionary parties managed to win the adherence of large numbers of followers; others urged us to see popular participation in revolution as rooted in the structures and culture of the popular classes and therefore quite separate from the concerns expressed by revolutionary elites. The empirical difficulty in getting these connections right remained a challenge in studies of particular revolutions, let alone efforts at comparative statement. Poorer, anonymous participants not only often lack the means to make their own wishes widely known (peasants seizing land are less likely to hold press conferences or write memoirs than are revolutionary agriculture ministers), but are, also as usual, often highly motivated to conceal their intentions (especially in highly charged situations like revolutions). It is a major methodological problem that revolutionaries who claim to speak on behalf of, say, Central American peasants, are rarely peasants themselves. Ethnographic fieldwork seems a promising methodology for contemporary cases in which researcher access is possible, but in revolutionary circumstances it is not always possible and it will not help a bit for past instances.
- *attention to the outcomes of revolutions*: The consequences of revolution for economic well-being, state power in the international arena, the rationalization of administration, national identities, citizenship rights, and democratization remain intensely controversial matters about which relatively little systematic investigation has been done by comparativists. In contrast to approaches that place enormous weight on the ideologies revolutionaries take into revolution as blueprints for the future or that see the weight of preexisting structures as deeply constraining, Arthur Stinchcombe (1999) has considered revolution as a process in which new claimants to rulership face challenges that emerge as the old order breaks down and the new one is under construction. Such challenges include the frequently dubious character of their new legitimacy claims; the general climate of defiance and mobilization over which they are trying to preside; the significant role often played by armed force, including with some frequency the hostile attention of dangerous neighboring states; the poor functioning of the state they have conquered; and the widespread anxiety-generating uncertainty about what tomorrow may bring. Such circumstances, Stinchcombe argues, are hardly conducive to the give-and-take of democratic politics and far more likely to generate some form of authoritarian rule, despite the democratic claims some revolutionaries carry with them into the revolution. More recent research suggests that democratic outcomes of political transitions are far more likely when the prime mover of change is massive nonviolent opposition than in cases of violent seizures of power against a background of state collapse or victory in prolonged armed struggle (Chenoweth and Stephan, 2011). There seems a broad agreement among scholars that revolutions commonly result in a strengthened state, a deeply ironic generalization since this has not been a common component of revolutionaries' visions (Goldstone, 2009).

  Regardless of the precise outcome, in light of the great diversity of interests and views of the multiple social groups that recent scholarship sees participating in revolutionary processes, those outcomes are highly likely to be very different from what many hoped for, a very simple explanation for the common occurrence of claims that our revolution has been hijacked. The terms 'success' and 'failure' commonly enter into discussion of revolutions. But if diverse participants have their own criteria for success, and if, moreover, these shift over time, the meanings of these terms might vary among actors and over the months and years. This suggests paying more attention to outcomes, to the consequences of revolutions in all sorts of realms and considered on a range of time scales. Just what the Russian Revolution brought about looked different in 1925, 1935, 1975, and 1995, for example. The outcome of revolution remains a wide open and still understudied field of inquiry.
- *renewed attention to process, at both micro- and macrolevels*: As scholars have become more critical of structural accounts, they have been more inclined to attend to human agency. They have therefore been examining individual participation in revolutionary events not as some automatic consequence of some fixed set of interests nor as the imperative of some preestablished ideology, but as a series of decisions that in a moment of crisis might even be taken day by day on whether to hang back or join in, decisions taken in response to swiftly changing decisions by other actors.

Kurzman (2004) has provided such an analysis of the mobilization of oppositional crowds that propelled the departure of the Shah of Iran. Markoff (1996) showed how during the French Revolution, the interaction of village mobilizations and legislative enactments radicalized both parties over a period of months.

On a more macrolevel, students of many particular revolutions have long noted the centrality of warfare to the dynamics of that revolution. In the revolutionary state, conflict among contenders to power may feed into the strengthening of military capacities and the development of an apparatus of surveillance and control. Revolutionary ideals may support extending the benefits of the new order abroad. Relations with other states may be managed by people inexperienced in such affairs. For their part, the dominant strata in neighboring states, fearful of the revolutionary vision and seeing the turmoil of the revolution, are led to be both motivated to crush it and to wildly underestimate the difficulty of doing so. Long-standing interstate conflict may take on a new dimension when one of the states has a new revolutionary regime. Tensions may be exacerbated if émigré groups have successfully sought refuge in neighboring states and are working to reverse the revolution and if opposition movements in those states seek the support of the revolutionary neighbors (Walt, 1996). The resulting warfare in turn often powerfully shapes the revolution in ways with little connection to the initial dreams of revolutionaries.

Some scholars, therefore, see revolution as a process in which interests are reshaped and ideas emerge in response to unanticipated situations that follow the collapse of the established order. Attention needs to be paid to the contingencies of rapidly developing situations and not just the structures and cultures developed over past decades or even centuries. This means as well that a sociology of revolution needs to recognize 'the power of events' (Sewell, 1996: 262).

- *how to integrate accounts of revolution with other kinds of political conflict*: Scholars of revolution were increasingly making use of tools that resembled those used by other students of politics: attending to the play of threat and opportunity, the variety of resources, the forging of identities in struggle, the irony of unintended consequence, the gaps between elites and ordinary participants (and the interaction between the two). Increasing interchange with scholars of other modes of conflictual action (urged by McAdam et al., 2001) was emerging. Jack Goldstone (2009) noted the convergence of social movement studies and studies of revolution. This convergence may be redefining the subject matter away from an exclusive attention to political transformations accompanied by violence toward a broader subject matter: the efforts of human beings to deliberately redesign their institutions; the great variety of means deployed in such efforts; and the contingent outcomes, both desired and undesired.
- *how to make superior use of comparative methodologies*: With increasing recognition of the complexity and diversity of revolutionary processes, the very logic of comparison was coming under heightened scrutiny. If revolutions are complex amalgams of multiple conflicts, some comparativists suggest that rather than searching for some single general cause, or some single general process, or some set of causes whose separate contributions to revolution may be simply added together, there may be multiple configurations of causal processes that produce revolutions, which themselves unfold in a variety of ways. Some scholars sought to distinguish varieties of revolution about which valid generalization might be made. Others suggested that the way forward, theoretically, was to seek generalizations about much smaller processes, which were components of revolutions, but which combined together in so many distinct ways as to defy generalization on that concatenated level. Some studies have made some use of formal methods for studying varying configurations (Wickham-Crowley, 1992; Foran, 2005).
- *change and continuity*: Revolutions are commonly experienced as moments in which people attempt to deliberately improve the workings of social institutions. They, therefore, provide a collection of instances in which to assess the extent to which those institutions are effectively altered in accord with deliberate design, remain unaltered despite efforts to do so, or are altered in unintended ways, thanks to the complexity of revolutionary processes. Opponents of revolution have commonly asserted both the futility of deliberately trying to reshape institutions and the perverse effects of efforts to do so (Hirschman, 1991).

  By the late twentieth century, some scholars were arguing that the dynamics of transnational structures of domination meant that the projects of revolutionaries who had managed to gain control of particular nation-states were so deeply constrained by those transnational structures that the effective levers for generating deep change were not to be found at the national level. Strong support for this view is provided by the world-system perspective developed by Immanuel Wallerstein and others (Wallerstein, 1990). Some scholarship on revolution was adding to the typical methods of comparative work that is built around resemblances and differences among distinct national cases, by examining as well the interaction of events and processes in different places, especially in the concept of an 'Atlantic Revolution' of the late eighteenth and early nineteenth centuries within which a wide variety of interacting European and American struggles were components. This approach, associated with the mid-twentieth-century work of Palmer (1959, 1964), was increasingly influential in the early twenty-first century (e.g., Adelman, 2006). Students of the social movements of the twenty-first century were also paying attention to processes that transcended the boundaries of individual states, as with the 'Arab Spring' of 2010–11.
- *rethinking the concept of revolution for the twenty-first century*: Along with revisiting the revolutions of the past, and rediscovering the complexity of their conflicts, their embeddedness in transnational processes, their visions, and their cultures, some were asking with Callinicos (2008), "What does revolution mean in the twenty-first century?" Equating revolution with the violent seizure of power in a crumbling state or with a military victory after protracted

armed struggle seemed inadequate for the emerging trends. The frequency with which political regimes are overturned by largely nonviolent mass civil opposition, whether quickly mobilized or long developing, suggested the study of a much more diverse array of instances. The increasing propensity of activists to mobilize transnationally to confront global processes suggested that the achievement of national power might come to be displaced as a defining characteristic, too. The often disappointing character of revolutions past was, by the turn of a new century, leading students of revolution to speculate on "How Might the Revolutions of the Future Have Better Outcomes?" (Foran, 2003: 284).

> Social activists in the early twenty-first century were increasingly thinking in terms of issues that transcended boundaries and seemed increasingly likely to think that the route, if there is a route, to transcending globalized capitalism lay in concerted action across rather than within national frontiers. To the extent that they were envisioning a radically different global order, they were suggesting that if there were to be a revolution for the new century that it would need to be envisioned on a larger geographical scale than the nation-state (Smith and Wiest, 2012). The revival of anarchist traditions, a striking presence in many of the social movements of the early twenty-first century, also suggested ways of thinking about revolutionary transformation other than seizing the state (Bamyeh, 2009). Wright (2010: 273–365) proposes directing theoretical attention more broadly to the variety of transformative processes. These might be 'ruptural' in the sense of a sudden access to power, very likely generating considerable violence and including common notions of revolution inherited from the past. But they also might be 'interstitial,' the development of new institutions and practices that bypass the state, or 'symbiotic,' carried out in partnership with an existing state, the sorts of programs commonly thought of as reforms. So, while many scholars had returned to a notion of revolution as something that, if not an everyday experience, had happened many times in many places, others were trying to discern the form of a singular large but multifaceted process transcending national boundaries that may lie ahead.

Conclusion

More than two centuries of reflection since 1789 have hardly exhausted the stimulation provided by revolution to the thinking of social scientists; if anything, since the 1970s there has been a tremendous intellectual reinvigoration. This is likely to continue, for revolutions seem a particularly privileged terrain for many significant issues in macrosociology, among which I indicate four:

- the intermingling of change and persistence;
- the interplay of long-run and short-run processes;
- the relationship of local, national, and transnational processes; and
- the collision of hopes for change and recalcitrant realities.

Revolution brings to the fore all the many issues that have swirled around the interplay of 'structure' and 'agency.' Whatever else they may be, they are social processes that strikingly juxtapose the capacity of human beings to construct for themselves previously unrealized and unexpected patterns alongside the incapacity of human beings to construct their world as they please.

Rhetorical Analysis

Peter Larsen, University of Bergen, Bergen, Norway

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Rhetoric is the old *art of oratory*. Originally a theory of speaking in public with special focus on argumentation and persuasion, it gradually became associated with poetics and stylistics of written texts. During the last century several attempts have been made to revive rhetoric, making it a part of a general communication theory. The first part of the article traces the history of rhetoric from classical antiquity to the late nineteenth century. The second part of the article presents four major trends in modern rhetoric. (1) *Rhetoric and semiotics*; (2) *Visual Rhetoric*; (3) *Metaphor, metonymy, and mental mapping*; and (4) *Rhetoric, argumentation, and thinking*.

Rhetorical Analysis

Rhetoric, the *art of oratory*, was developed in ancient Greece and Rome. Both as a general communication theory and as a collection of practical advices on how to convince an audience, rhetoric exerted decisive influence on the history of Western civilization and culture. In the period from antiquity until the nineteenth century, rhetoric was the single most important subject taught in Western educational institutions. During these more than 2000 years it changed both in scope and perspective. Corresponding with the growth in written communication, it was gradually transformed into an *art of writing*. In later centuries it became closely associated with the writing of literature, while less emphasis was put upon argumentation and persuasion.

Rhetoric deals with communicative situations. Speeches and texts are always considered in their relation to the aims and intentions of the speaker/writer, the subject matter in question, the general mood and prior knowledge of the expected audience, etc. Correspondingly, any kind of analysis that sets out to describe the ways in which a given discourse is determined or affected by its immediate communicative context could be said to be rhetorical in nature. Rhetorical analyses of this kind have always played an important role in literary studies, but during the last few decades similar methods have also been applied to nonliterary texts and even to nonverbal means of expressions, for instance, in connection with studies of political propaganda, advertising strategies, as well as mass media in general.

The History of Traditional Rhetoric

Classical Antiquity

Some ground rules of oratory were developed and taught by Sicilians in 485 BC in connection with legal disputes about real estate. This rudimentary rhetoric quickly spread to Athens where a more comprehensive body of knowledge about the art of public speaking was developed from the mid-fifth century and onward. Greek rhetoric was introduced in Rome in the first-century BC as part of the education of older children.

In the Greek period, the so-called Sophists – persons who taught rhetoric, politics, and mathematics for money – played an important role in the development of rhetoric as a formal discipline. They were attacked by Plato for putting more emphasis on style than on substance. Plato's critique raises a question, which has followed rhetoric ever since: Is rhetoric a method for discovering the truth, or merely an effective manipulation technique? Is rhetoric being used in order to convince or to persuade the audience?

There is, however, no clear answer to these questions. The old Greco-Roman rhetoric – as described by Aristotle (384–322 BC; *see* Rhetoric), Cicero (106–143 BC; De Oratore), and Quintilian (*c*. AD 35–95; Institutio Oratoria) – was a complex social system of interrelated, and in some cases even contradictory, practices (cf Barthes, 1970; Vickers, 1988). First of all, rhetoric was an art in the classical, Aristotelian sense of the word, i.e., *a craft or technique*, a collection of rules and advices for speakers who want to convince or persuade an audience. These rules were taught in and transmitted through strong educational institutions. Thus, rhetoric was also a discipline, a *subject*, a body of knowledge. In addition, this body of knowledge constituted a *theory*, or at least a semitheoretical field; it described and classified some important effects of verbal language.

The Rhetorical System

The old manuals divided rhetoric into five parts: *Inventio*, *Dispositio*, *Elocutio*, *Memoria*, and *Actio*. Each part covers a specific field of knowledge and aims at training certain skills related to the field in question.

- *inventio* (finding what to say) is the part dealing with *argumentation*. Speakers learn to analyze a given subject matter, to find relevant information, and to determine which types of information are the most useful for their purposes. They also learn to convince an audience with quasilogical proofs (*logos*), and to move the audience by appearing to be good and trustworthy (*ethos*) or by stirring the audience's emotions (*pathos*).
- *dispositio* (organizing what one has found) deals with *composition*. Speakers learn to organize their speeches in clearly separated sections.
- *elucutio* (choosing the proper words) is the part that deals with verbal *ornamentation*. Some elementary rules are presented together with examples of striking images and other verbal devices, which can be used to color a text.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95031-1

- *memoria* (remembering what to say) is an introduction to *mnemonics*.
- *actio* (performing the speech) contains practical advices on how to *deliver* a text before an audience.

The Reduction of Rhetoric

The memoria and actio parts were rather sketchy in the old manuals, and because they were directly related to the practice of oratory, they disappeared as soon as rhetoric became a theory of written discourse. During the Middle Ages the tripartite system of inventio/dispositio/elocutio was taught together with grammar and logic. This system collapsed during the seventeenth century, and rhetoric ended up being a part of poetics. From now on it was further reduced: inventio and dispositio, the parts most closely associated with logic and argumentation, lost in importance and in the end all that remained of the old system was elocutio, the part dealing with questions of stylistics.

The *elocutio* sections of the old manuals taught the reader that significant persuasive or poetic effects can be obtained by selecting the proper words and combining them in the right manner. A flat statement of facts can be transformed into a strong, colorful, and convincing message by the use of *tropes* or *figures*, i.e., by substituting single words (*tropes*) or by manipulating phrases consisting of several words (*figures*). However, when eighteenth-century linguists and literary theorists began to study and classify the many varieties of discursive ornamentation, they found that most of these poetic effects could be described as variations of two semantic relations, viz. *similarity* and *contiguity*. The similarity relation finds its clearest expression in the *metaphor*, while *metonymy* and *synecdoche* are well-known examples of ornaments based on causal and spatial contiguity relations. From the eighteenth century and onward, metaphor gradually became a kind of supertrope representing all the other tropes and figures based on similarity relations, while metonymy correspondingly became the representative of all the various ornaments based on contiguity relations (Genette, 1970).

Modern Rhetoric

Rhetoric and Semiotics

During the twentieth century several writers sought to incorporate this reduced version of traditional rhetoric into a broader, more general framework. One of them was the Russian linguist Roman Jakobson who in 1956 presented a structuralist interpretation of *elocutio*, arguing that the metaphor–metonymy dichotomy corresponds with a general bipolar structure in language (Jakobson, 1956). All discursive production is the result of two fundamental linguistic processes based on similarity and contiguity. These metaphoric and metonymic poles in language can be observed in all normal linguistic behavior but, Jakobson argued, they are also manifest in any symbolic process, either intrapersonal or social (for a fuller discussion of the metaphor–metonymy dichotomy, see the following section).

Jakobson thus opened the field of rhetoric toward sign systems other than language. His own examples included the dream work studied by psychoanalysts, the magic rites described by anthropologists, as well as nonverbal forms of art like cubist painting, the films of Chaplin and Eisenstein, etc.

Jakobson exerted decisive influence on French structuralists and semioticians during the 1950s and 1960s, among them Roland Barthes who in a seminal article, *Rhetoric of the Image*, proposed to rethink classical rhetoric in structural terms (Barthes, 1964; *see* Semiotics). Like Jakobson, he argued that the immense variety of tropes and figures categorized by traditional rhetoric are merely surface manifestations of a few formal relations that can be shown to be the structural armature in all kinds of verbal discourse as well as in several nonverbal forms of expression. He predicted that it would be possible to establish a general rhetoric, which would be valid for all types of discourses, for texts as well as for sound and images.

Since the 1960s there have been several attempts at implementing Barthes' project.

The most comprehensive contribution is the work of the so-called *Groupe* μ, a group of Belgian researchers, who presented a general description of rhetorical tropes and figures on a semiotic/structuralist basis (cf Groupe μ, 1970).

The semiotic-structuralist interpretation of traditional rhetoric was mainly a theoretical project, but it had important practical and analytical consequences as well. In his 1964 article, Barthes argued that there is a close connection between rhetoric and ideology, a view supported by the fact that the classical manuals usually were more concerned with probabilities than with the actual truth of the matter. In order to be convincing one must know one's audience, know what people will or will not accept as probable, in short one has to respect *doxa*, i.e., public opinion, the stereotypical forms of thought that members of the audience rely on in their everyday lives. This means that the rhetorical devices used in a text can be understood as discursive expressions – or exploitations – of dominant ideologies within a given society and that such ideologies can be brought to light by means of rhetorical analysis.

That rhetorical analysis can be used as a decisive critical tool had already been proven by the American critic, Kenneth Burke who in 1939 wrote an influential article on the argumentative strategy in Hitler's *Mein Kampf* (Burke, 1941; see also Burke, 1962). From the 1960s and onward, Barthes and many other writers followed Burke's example and made rhetorical analysis a part of a general critique of ideology. Using the insights gained by the fusion of semiotics and rhetoric they made systematic studies of the patterns and systems of belief that are presented as 'natural' or 'evident' in newspapers, fashion magazines, popular films, television programs, etc. This form of analysis was particularly efficient in studies of advertising (for an overview see Dyer, 1982).

Visual Rhetoric

The question of visual rhetoric is central to many works in the semiotic/structuralist tradition. One early example is Jacques Durand's study of advertising in newspapers and magazines (Durand, 1970[[1983]], 1987). Durand reorganized the classic list of linguistic tropes and figures by defining them as transformations of 'simple' propositions into 'figurative' ones. He argued that these building blocks of traditional rhetoric could

be classified by taking two parameters into account: (1) the particular type of transformation – addition, suppression, substitution, and exchange – and (2) the relations – of identity, similarity, difference, and opposition – between the original and the transformed elements. Using this classificatory grid while analyzing a comprehensive corpus of advertisement he showed that it was possible to find modern, visual parallels to all the linguistic tropes and figures described in the classic rhetorical manuals.

Several other scholars have followed Durand's example and proposed similar or more differentiated classifications and typologies (see for example McQuarrie and Mick, 1999, 2003; Philips and McQuarrie, 2004). In a similar perspective, the Belgian Groupe μ has presented a general description of all conceivable types of visual signs aiming at establishing an exhaustive 'rhetoric of the image' (Groupe μ, 1992).

Durand's classifications of visual tropes and figures as well as some of the later typologies have been criticized for using linguistic rhetoric as the basic model, for not taking the special nature of images into account, and for not focusing on the special argumentative force of images. In his work on visual persuasion the US media scholar, Paul Messaris has, in contrast, emphasized the differences between visual and other forms of communication (Messaris, 1997). Describing the role of images in persuasive communication, Messaris points to three fundamental characteristics:

- *Iconicity*: Images can simulate visual reality and evoke attitudes and emotions associated with real people, objects, places, and situations.
- *Indexicality*: Due to the nature of analogue recording, photographic images can function as proof of and support for linguistic statements.
- *Syntactic indeterminacy*: In contrast to linguistic statements, images cannot propose explicit arguments. Since visual arguments are indirect and blurry, it is difficult to argue against them.

These features give images a particular rhetorical strength: While linguistic statements can be checked and tested, images can suggest and hint at propositions that cannot be formulated explicitly. The special relations between text and images in advertising have been analyzed by Leiss et al. in a study of two Canadian magazines from the 1890s to the present (Leiss et al., 2005). Using a combination of semiotic textual analysis and quantitative content analysis the authors study the changing rhetorical strategies in advertisements during the period. They show that not only has there been a major shift from text to images during this period, but also the rhetorical function of the images has changed considerably. The rhetoric of the early phase was characterized by a primarily textual, quasilogical praising of the products and their qualities with images being used as mere illustrations. During the 1920s, as potential buyers became more sophisticated readers of advertisements, this strategy gave way to an indirect, but still primarily textual, argumentation based on suggestions and associations that situate the products in networks of abstract, symbolic qualities. The images became the dominating element during the 1950s and were used to imply that products can change the way in which buyers are perceived by other people. From the 1960s and onward the chief function of images have been to associate the products in question with attractive social groups and lifestyles.

Metaphor, Metonymy, and Mental Mapping

Elocutio was the only part that was left of the old rhetorical system by the beginning of the twentieth century. There was, however, a growing interest in this surviving part and particularly in metaphor. Not only did metaphor become one of the most studied subjects in literary theory, but also the interest spread to several other areas. At present the study of metaphor is one of the most fertile fields in the humanities and the social sciences. It plays a crucial role in academic disciplines as diverse as linguistics, film and media studies, constructivist psychology, anthropology, and cognition theory.

During the last century the conception of metaphor has changed dramatically. From being a poetic device producing a specialized type of discursive effect, it is now generally regarded as a very fundamental mental tool: "the essence of metaphor is understanding and experiencing one kind of thing in terms of another," as George Lakoff and Mark Johnson put it in their book *Metaphors We Live By* (1980). Metaphor is the kind of understanding, which is produced when a set of relations is displaced from one kind of thing to another. Or to put it another way: Metaphor is a type of *mental mapping*. When people say that 'time is money,' they establish a simple relation of similarity between two elements but this process entails a further mapping of a whole series of relations from the time-field onto the money-field: if time is money, then time must also be valuable, scarce, etc.

According to Lakoff and Johnson there are three major types of metaphor. One is the *structural metaphor*, the 'time is money' variety just mentioned: a restricted, almost local, structuration of one field in terms of another. Another one is the *orientational metaphor* which is used to give larger systems of concepts a spatial orientation. When for example happiness is described as 'being up' and sadness as 'being down,' a spatial relation (up/down) is mapped onto an emotional relation (happy/sad). Such orientational metaphors are clearly grounded in very concrete, physical experiences of the body and its position in space. According to Lakoff and Johnson all metaphors do actually have some kind of concrete experiential basis. One example is the third major type, the *ontological metaphor*, which is based on the everyday experience of handling physical objects. Ontological metaphors make it possible for an individual to understand – and thereby to deal with – events, activities, emotions, ideas, etc. as if they were objects, entities, or substances.

Metonymy, the other supertrope, does also have important cognitive functions. Its basic principle is that one entity *stands for* another. In the phrase 'sails on the water,' a part (sail) is used as a shorthand reference to a totality (boat). Thus, a metonymy emphasizes or highlights certain aspects or features within a given totality. In the very act of referring, metonymy thereby serves some of the same purposes as metaphor does.

Metaphor and metonymy are mental tools which enable people to focus their everyday experiences and to understand the world they live in. They are, as Lakoff and Johnson point out, part of the ordinary way in which people think, act, and

talk. Sometimes we use these tools in new and original ways, but most of the resemblances we perceive and most of the shorthand references we make in our everyday lives are the result of relatively conventional metaphors and metonymies that have become part of our conceptual system. In later years, there have been a growing number of studies of such conventional metaphor/metonymy-based systems and the role they play in public debates and political communication. One striking example is George Lakoff's own analysis of the political rhetoric used by US politicians in the weeks before the war in the Gulf in 1991 (Lakoff, 1991). In a later work, Lakoff argues that the metaphors used in political discourse function as 'frames' that actively shape and influence the ways in which an electorate thinks about the issues in question (Lakoff, 2004).

Rhetoric, Argumentation, and Thinking

Traditional rhetoric originated in relatively small, closed societies characterized by limited flows of information. Politicians and lawyers who should speak in public were faced with the task of convincing or persuading uneducated and incompetent audiences. The manuals told them how to do that.

Communication today is still a question of finding and interpreting relevant information and presenting it in effective ways. Nevertheless, the general communicative situation has changed radically since the days of classical antiquity. The most important communication is mediated by radio, films, television, the Internet, etc. – media characterized by what has been called a new type of orality (Ong, 1982). Information is distributed at an incredible speed, and the total amount of available information is growing rapidly. Even though the general level of education is considerably higher than any time before in the history of the world, a modern mass audience is a rather heterogeneous phenomenon consisting of people with very varying degrees of knowledge and competence.

The fear that this complex situation with its rapid flow of information may result in massive manipulation of the audiences provides a significant background for many of the newer attempts at reviving rhetoric. One example is the so-called *New Rhetoric* which was developed in the mid-twentieth century (Perelman and Olbrects-Tyteca, 1958; Toulmin, 1958). The New Rhetoric was initially an attempt at reestablishing the total rhetorical system in order to be able to cope with all aspects of the new, media-driven types of communication. However, from the very beginning the strongest emphasis was put upon *inventio*, and more specifically on *argumentation*, one of the parts of traditional rhetoric that more or less had disappeared when rhetoric became associated with literature and poetics.

In the philosophical tradition argumentation has usually been associated with logic and the techniques of deduction and induction. What the New Rhetoricians have in mind, however, is not this strict, formal, and logical type of argumentation, but the 'fuzzy' thinking, the jumping-to-conclusions known from everyday life. Aristotle excluded this kind of thinking from logic proper but included it in his Rhetoric and actually considered it to be one of its most important parts.

Rhetorical argumentation is a 'situated' form of argumentation; it cannot be performed or understood without taking the total communicative situation into consideration. It is dependent on the subject matter, the level of available information, the preexisting attitudes and prejudices of the speaker and the audience, the type of media which is used, etc. In short, what is at stake here and what the New Rhetoricians as well as many other, later writers (cf for example Billig, 1987) set out to describe and analyze, are the various ways in which practical, everyday reasoning is determined by its immediate context.

Viewed like this rhetoric is much more than a theory of oratory or a collection of simple rules to be used by poets – it is a discipline which studies the underlying principles governing all human discourse, the way in which people argue with themselves and with others, the way in which they make value judgments, etc. Rhetorical analyses of such arguments and of how judgments are made can provide a better understanding of how opinions and social attitudes are formed in complex modern media-driven societies.

Rheumatoid Arthritis: Psychosocial Aspects

Christina Bode and Erik Taal, University of Twente, Enschede, The Netherlands

Abstract

Rheumatoid Arthritis (RA) is a chronic inflammatory disease, which is accompanied by swollen and painful joints, fatigue and limitations in physical functioning. Psychological reactions to disease symptoms and related attitudes and psychological characteristics of patients clearly influence the impact of disease symptoms on psychological distress and well-being, on daily activities and on social participation. In addition to pharmacological treatment of disease activity, regular monitoring of patient-reported symptoms and timely psychological stepped care approaches seem the best way to support and empower patients to successfully adapt to RA and to live a meaningful life with RA.

Rheumatoid Arthritis: Etiology, Prevalence, Course and Disease Management

Rheumatoid Arthritis (RA) is a chronic inflammatory disorder based on an autoimmune process. The immune tolerance for the own body is broken down and the (chronic) inflammatory reaction affects cartilage, joints and bones, and possibly other organs.

The course of the disease is heterogeneous. It ranges from mild courses without bone erosion and spontaneous remissions to severe, rapidly progressive forms with damage of joints, disability, and high negative impact on quality of life.

Relevant factors discussed for the etiology of RA are genetic predispositions in interaction with environmental factors that determine the immune response and inflammatory reaction. As important environmental factors mainly two aspects have been discussed: infections might start the autoimmune response and cigarette smoking increases the risk of developing RA and is associated with more severe forms of the disease. In addition to environmental factors, hormonal and reproductive factors may play a role in the development and severity of RA, suggested by the fact that clearly more women than men are affected by RA (Kvien et al., 2009).

RA affects 0.5–1.0% of adults in developed countries; it is more frequent in women (3:1) and prevalence rises with age (Scott et al., 2010).

Pharmacological treatment aims at the control of disease activity, in the best case this means remission to prevent joint damage and minimize pain, fatigue, disability, and reestablish social and work participation. If remission is not achievable, the pharmacological treatment aims to reach and maintain the lowest possible level of disease activity as soon as possible in every patient. As long as this target has not been reached, treatment should be adjusted by frequent and strict monitoring (European League Against Rheumatism recommendation for management of RA: Smolen et al., 2010).

Nonpharmacological treatment for RA includes patient education, exercise therapy, joint protection, psychological support, and foot care. Ideally, multidisciplinary teams of rheumatologists, nurses, physiotherapists, occupational therapists, psychologists, and podiatrists deliver holistic care for patients with RA. In reality, however, only very few specialized hospitals offer multidisciplinary team care for RA patients.

Psychophysical Aspects of RA: Pain, Fatigue, and Physical Functioning

Pain

Patients with RA perceive joint pain as one of the most important problems of their disease (Taal et al., 1993; Walsh and McWilliams, 2012). Pain is caused by inflammation and structural damage of the joints. In a 10-year longitudinal study (with measurements at baseline and after 1, 2, 5, and 10 years) of patients with recently diagnosed RA the mean pain score of the patients on a visual analog scale from 0 (no pain) to 100 (severe pain) was between 28 and 33 on all measurements over time. At all time points, 30–35% of the patients had clinically relevant pain scores $\geq$40 (Odegard et al., 2007). Patients with RA see pain as their highest priority for improvement, although it may improve over time (Ten Klooster et al., 2007). Modern early and intensive pharmacological treatments lead to successful suppression of inflammation and improved levels of pain (Walsh and McWilliams, 2012).

Next to inflammation and structural damage, psychological factors may influence the experience of pain (Walsh and McWilliams, 2012). Odegard et al. (2007) showed that over 10 years anxiety was longitudinally associated with the course of pain. Schieir et al. (2009) found that also baseline depression predicted the course of pain from baseline to 6 months in patients with early inflammatory arthritis. In a 1-year longitudinal study feelings of helplessness and passive coping significantly mediated the relationship between physical disability and future pain in patients with RA (Covic et al., 2003). In a study with weekly measures over a duration of 11 weeks anxiety, depression, and negative and positive affect predicted weekly changes in pain in patients with RA and osteoarthritis. The effects of anxiety on pain were much stronger than the effects of depression. Remarkably, the effect of anxiety on pain was mediated by negative affect and the effect of depression was mediated by positive affect (Smith and Zautra, 2008). Lower social support was related to increased pain after 3 and 5 years in patients with recently diagnosed RA. Contrary to expectations passive pain-coping was not related to increased pain levels (Evers et al., 2003).

The role of psychosocial factors in the experience of pain indicates that, next to pharmacological treatment, there is a role for psychological interventions for the management of pain.

Self-efficacy beliefs of patients (that they can manage their pain) and the actual use of pain-coping strategies influence pain experiences and also the impact of pain on physical function and psychological distress (Keefe et al., 2008). Several studies have shown that pain-coping skills training and cognitive behavioral therapy can be successful in reducing pain. Furthermore, it has been shown that these interventions also lead to improvements in anxiety, depression, and physical function (Keefe et al., 2008).

Fatigue

Severe fatigue is commonly reported by patients with RA. Prevalence of severe fatigue differs depending on studied sample and measurement instrument; 40–80% of patients diagnosed with RA report persistent fatigue symptoms (Wolfe et al., 1996; Pollard et al., 2006). Qualitative research from different countries has shown that patients experience fatigue as a multidimensional, annoying symptom with far-reaching consequences (Hewlett et al., 2005; Repping-Wuts et al., 2008; Nikolaus et al., 2010). Physical, cognitive, and emotional aspects of fatigue have been described, and also perceived causes and consequences of fatigue. Additionally, interindividual and intraindividual variations in fatigue severity and the uncontrollability of fatigue symptoms were found as important dimensions from the patient's perspective.

Fatigue influences fulfillment of social roles and participation negatively: functioning as parent, partner, friend, and also in the work domain. Fatigue was identified as an important predictor of work absenteeism and early retirement (De Croon et al., 2005). In contrast to the far-reaching consequences and the priority from patient perspective, fatigue plays no role in treatment decisions and is mainly neglected in the communication between health care providers and patients. This might be explained by the fact that the knowledge about the etiology of fatigue symptoms is very limited.

A systematic review (Nikolaus et al., 2013) provides an overview of the existing literature on possible causes and consequences of fatigue in RA. Studies report possible causes for fatigue among illness-related aspects (pain), physical functioning (sleep quality, sleep disturbances, global health ratings, disability), cognitive/emotional functioning (depression, anxiety, perceptions as self-efficacy), social/environmental aspects (interpersonal events, social support), and female gender. However, none of these variables showed profound and stable relationships with fatigue across studies. Inconsistent results were especially reported with regard to inflammatory activity (e.g., ESR, DAS28, flares). Moreover, it is unclear how the proposed directions between fatigue and the other variables correspond with the real processes. Probably, multiple, circular processes underlie fatigue in RA (Hewlett et al., 2011), so that it is not possible to identify single causes of fatigue without considering interactions with other potential pathways. Nicassio et al. (2012) found some cross-sectional evidence for an indirect relationship of disease activity and fatigue through its effects on mood disturbances and poor quality of sleep. Based on the systematic review of Nikolaus et al. (2013), three variables have the highest probability to be involved in the complex process of fatigue in RA: pain, physical functioning, and depressive mood.

Fatigue has scarcely been studied as primary outcome of pharmacological treatment. A meta-analysis by Chauffier et al. (2012) has demonstrated that the effects of biotherapies on fatigue in RA are very limited and that they fall short of the expectations with regard to the fatigue-reducing potential of new pharmacological treatment options. A review on non-pharmacological interventions provides some evidence that physical activity and psychosocial interventions have positive effects on self-reported fatigue in adults with RA, for other nonpharmacological interventions there is currently insufficient evidence for their effectiveness (Cramp et al., 2013).

Physical Functioning

The inflammation and structural damage of joints result in restrictions in physical function in patients with RA (Hazes, 2003). Physical function is the ability of a person to perform activities of daily living (ADL). In interviews with RA patients, functional disability ('not being able to do things,' 'mobility restrictions') was most often reported as one of the main problems of having RA (Taal et al., 1993). Recent studies showed that many concerns about the future of patients with RA are related to restrictions in physical functioning such as dependency on others regarding activities such as shopping or self-care, no longer being able to walk or to do leisure activities (Buitinga et al., 2012).

The golden standard to assess restrictions in physical function in patients with RA is the Health Assessment Questionnaire – Disability Index (HAQ-DI), which measures difficulties in activities that involve both the lower and upper extremities. It has questions in eight categories of ADL's that can be affected by RA: dressing and grooming, rising, eating, walking, hygiene, reach, grip, activities (errands, chores) (Bruce and Fries, 2003). These categories cover most domains of physical function that have been identified in the International Classification of Functioning, Disability and Health (ICF) core-set for RA (WHO, 2001; Oude Voshaar et al., 2011). About 10% of patients with RA score 0 on the HAQ-DI meaning they have no difficulties in performing activities in all eight categories of daily living (Krishnan et al., 2004). Patients with short disease duration often have relatively high restrictions in physical function mainly related to high levels of disease activity. After start of medical treatment, physical function initially improves followed by a slow decline in physical function over the years, mainly related to increased joint damage (Verstappen, 2013). Recent advances in pharmacological treatment of RA have shown large improvements in physical function after treatment, especially in patients who achieve clinical remission (Kekow et al., 2011). Restrictions in physical function tend to increase with age and are slightly higher in women than men. Also comorbidities (such as cardiovascular or respiratory diseases), low socioeconomic status, and low educational levels are associated with worse physical function (Verstappen, 2013).

The decline of physical function over time is also affected by psychosocial factors (Hazes, 2003). Depressive symptoms were related to physical disability, but they were not predictors of changes in disability over 2 years in patients with RA (Rupp et al., 2006). Kekow et al. (2011) reported that patients with severe symptoms of depression or anxiety (HADS scores ≥ 8)

before starting pharmacological treatment of RA had significantly worse physical function and achieved considerably less improvement in physical function after 2 years of treatment compared to patients without symptoms of depression or anxiety. Evers et al. (2003) showed that the use of more passive pain coping and having less social support is related to increased physical disability after 3 and 5 years in patients with recently diagnosed RA. Worse physical function is related to higher work disability (Young et al., 2002) and more psychological distress (Norton et al., 2011) over time, and is a strong predictor of mortality (Sokka et al., 2008).

There is some evidence that exercise programs and occupational therapy improves physical function in RA (Vliet Vlieland and van den Ende, 2011). A systematic review of the effectiveness of patient education programs for patients with RA shows small beneficial short-term effects on physical function, especially for programs that included behavioral instructions. However, no long-term effects on physical function were found (Riemsma et al., 2004).

Psychological (Dys)functioning: Depression and Anxiety

In the previous paragraphs we have described that pain, fatigue, and limitations in physical functioning are associated with depressive symptoms. Therefore, we now take a closer look at depression. Depression is a frequent comorbidity in RA. Prevalence of depression depends on studied population, used measures, observation time, and culture/country, but in general the levels of depression are clearly elevated compared to rates of depression in populations without RA. According to a recent systematic review and meta-analyses of 72 studies on the prevalence of depression in adult RA patients (Matcham et al., 2013), prevalence rates vary between 17 (major depressive disorder, using clinical interviews) and 39% (significant depressive symptoms, measured with screening instruments).

Merely considering clinical levels of depression fails to document subclinical levels of depressive mood, which may constitute a transitional phase to clinical levels and also mean suffering for patients with RA. In addition, both clinical and subclinical levels of depression have serious health-related consequences. Poorer adherence, maladaptive health behavior, increase of RA symptoms, poorer functional outcomes, and lower satisfaction with social relationships (network size and quality of relationships) and social participation (work- and nonwork related) and finally more health care utilization are documented as related to depression. Few studies investigated the relationship between depression and mortality in people with RA. They found clearly higher risks for all-course mortality, increased risk of having a heart attack and other comorbidities (Scherrer et al., 2009; Ang et al., 2005).

Diagnosing and interpreting depression is complex due to the overlap of other RA symptoms (fatigue, sleep problems, reduced levels of interest, and pleasure in activities) and also because of the inflammation processes that might be associated with depression through elevated levels of cytokines (Geenen et al., 2012). With regard to interpretation, it is debatable whether short-term depressive feelings reflect a normal (adaptive) reaction to the diagnosis and consequences of RA for daily functioning. Patients with stable elevated levels of mood problems, however, should definitely be screened for depression and treated accordingly. Van't Land et al. (2010) investigated whether depression precedes RA. They found that people with arthritis are more likely to develop depressive symptoms compared to people without arthritis, whereas having any mental disorder did not predict the new-onset of arthritis. In younger age groups (<45 years of age) this relationship was even more pronounced. These results suggest that younger patients with RA are even more at risk to develop clinical forms of depression. Also the meta-analyses by Matcham et al. (2013) found that younger age was associated with increased depression prevalence.

Whereas depression has been investigated widely, anxiety seems to be an overlooked aspect of problematic psychological functioning in patients with RA. Although depression and anxiety have a substantial overlap (VanDyke et al., 2004, reported 69% shared variance) there are at least three reasons to investigate and monitor anxiety and depression separately. First, the prevalence of anxiety might be higher than the prevalence of depression (20–30% elevated levels of anxiety, Geenen, et al., 2012) and anxiety might have stronger effects on current and next week pain (twice as large according to Smith and Zautra, 2008). Second, different mechanisms of anxiety and depression on pain in arthritis patients have been postulated: while anxiety is assumed to affect pain through anxiety sensitivity, pain-relevant anxiety, and fear avoidance, depression and pain might be linked through catastrophizing less positive reinforcement and helplessness (Smith and Zautra, 2008). These assumptions, however, need more substantiation but they potentially imply different treatment strategies for anxiety and depression. The third reason is the possible temporal sequence with first anxiety followed by depression that would suggest more focus on anxiety to prevent depressive episodes (VanDyke et al., 2004).

In summary, a range of factors have been identified to be associated with distress for patients with RA, which might manifest in subclinical or clinical levels of depression and anxiety. Prominent candidates for developing mood problems are somatic symptoms, functional limitations, proinflammatory cytokines, helplessness, and fear for the future due to the unpredictable and progressive character of the disease.

Social Consequences: Social Participation and Work Participation

RA can lead to restrictions in participation in work and other social roles (Geuskens et al., 2007). The ICF Model of the World Health Organization defines social participation restrictions as problems an individual may have in involvement in life situations (e.g., looking after family members or doing paid work); they are distinguished from physical limitations a person may have in executing basic tasks (e.g., walking or washing/personal hygiene) (WHO, 2001). Geuskens et al. (2007) have shown that patients with RA are more restricted in work participation and socializing compared to the general population. In cross-sectional studies it was found that role and social functioning, as measured with the Short Form 36 (a self-report questionnaire that measures physical, mental, and social

aspects of health-related quality of life with 36 items (Ware and Sherbourne, 1992)) were associated with disease activity, pain, physical limitations, vitality, and mental health (Fransen et al., 2002; Kuhlow et al., 2010). In a recent study involving patients with polyarthritis, restrictions in social and work participation were cross-sectionally related to functional limitations and fatigue (Arends et al., 2013). This study revealed that also psychological factors were significantly associated to restrictions in social and work participation: self-efficacy in coping with arthritis and the use of goal management strategies (i.e., the way people generally react to threatened life goals) played an important role in the satisfaction with social participation. Katz et al. (2006) studied loss of participation in valued life activities (VLA), a concept that partly overlaps with social participation restrictions as defined by the ICF model. VLA are grouped into obligatory activities (e.g., hygiene and self-care, walking, using transportation), committed activities (e.g., paid work, household, and family care responsibilities), and discretionary activities (e.g., socializing, recreation, hobbies). Only restrictions that are deemed important by a patient are incorporated in individual total VLA scores. In a cross-sectional study among RA patients more restrictions in valued discretionary and committed activities were found than in obligatory activities. Difficulties in performing VLA could be predicted by higher age, being female, longer disease duration, and symptom measures such as fatigue, pain, morning stiffness, and feet deformities. In this study, relationships between symptom measures and difficulty in performing VLA were mediated by functional limitations (Katz et al., 2006).

Longitudinal studies are needed to gain better insight in the causal relationships between disease activity, symptoms as pain and fatigue, physical limitations and restrictions in social and work participation, and the role of psychosocial factors in this context.

Living a Good Life with Arthritis: Supported by Regular Monitoring and Timely Support

In the last decennium, modern pharmacological treatment strategies have contributed to meaningful progress in the treatment of RA. About 50% of remission in early RA patients has been reported, resulting in lower disability rates, less radiological damage, and also fewer patient-reported symptoms. Nevertheless, findings also indicate that the presence of elevated levels of depression or anxiety at start of treatment delays clinical remission (Kekow et al., 2011). This points to the fact that monitoring of psychological functioning and early intervention can even increase the potential of successful pharmacological therapies, which are directed at controlling disease activity.

While these advances in pharmacological treatment mean less impact of RA on their lives for a number of patients, for others it remains a challenge to deal with symptoms of pain, fatigue, decreased physical functioning, and fewer possibilities for social participation and use of their personal potential. Developing skills to manage RA symptoms and finding a new satisfying life balance can be supported in various ways. Patient education and self-management programs have been developed with the aim to enhance living well with RA. The results of these programs, however, are mixed. Many short-term effects cannot be shown to last over longer periods (>12 months). Unfortunately, many effect studies have focused on (medical) outcomes that were not targeted in the interventions, disadvantaging potential benefits of these programs. Iversen et al. (2010) have reviewed self-management interventions and have described common characteristics of effective programs: duration of at least 6 weeks, explicit use of social cognitive theory or cognitive behavioral therapy approaches, individualized action plans with progress review, highly protocolized with participant handbooks, and led by the same trained leaders.

Currently, frequent monitoring of patient-reported symptoms in combination with stepped-care approaches seems to be the best way to support and empower patients in dealing with arthritis. Also, shifting the emphasis from only treating psychosocial problems to enhancing patients in dealing proactively with their disease might prevent the negative downward spiral of physical, psychological, and social limitations and opens opportunities for a new meaningful life with RA (Arends et al., 2013). Savings in health care systems and focus on medical treatment rather than holistic approaches ask for creative and innovative solutions. E-health applications for monitoring and proactive self-management of patients have the potential to deliver a significant contribution. Whether this way of health communication and treatment can reach all groups of patients and can be supported by all health professionals is questionable. Tailoring the choice of communication and treatment channels to patients' capacities and also to opportunities of care providers might be necessary to prevent new inequalities in health care and diminish negative psychosocial consequences of RA as much as possible.

Abstract

David Ricardo is widely regarded as a founding figure in both classical economics and political economy alongside such figures as Adam Smith and Thomas Malthus. As a practicing financier on the London stock market, he brought his practical understanding of economics to basic problems in economic theory. Although his contributions to economics have often been criticized, his position as a founding father of the discipline is secure. A full-scale biography was published in 2013 and his collected works were edited by Piero Sraffa in 11 volumes (1951–73). Ricardo made important contributions to political debates in his time such as the corn trade. He made lasting contributions to both microeconomics and macroeconomics in the law of diminishing returns and to the labor theory of value; consequently, his work was much admired by Karl Marx. By recognizing that technological improvements could reduce the need for labor if not displace it, he anticipated what is now referred to as the de-skilling of labor. However, according to Paul Samuelson, Ricardo's major contribution was to the theory of comparative advantage, which says that, given international competition, an economy should specialize. Finally, Ricardo was a champion of free trade and the so-called *laissez-faire* economics. While Ricardo is highly regarded in economics, his contribution to the theory of social classes in his analysis of rent, profit, and wages has been neglected in sociology.

One of the most influential of the classical economists, David Ricardo was born in London in 1772 to a Sephardic Jewish family of Portuguese origin, who had emigrated from the Netherlands. At 14 years of age Ricardo joined his father at the London Stock Exchange, where he acquired a practical understanding of the actual mechanics of both domestic and international finance. These early experiences laid the foundation for his subsequent success in amassing a personal fortune. Rejecting the orthodox beliefs of his Jewish family, he eloped at 21 years of age with Priscilla Anne Wilkinson in 1793, a Quaker by whom he had eight children. On subsequently becoming a Unitarian, he was rejected by his family. The elopement and separation from his parents resulted in a period of personal hardship, forcing him to seek new means to support himself.

With his practical experience of finance, he became a highly successful stockbroker by unscrupulously trading on the bond market during the Battle of Waterloo in 1815. He was able to post an observer at the famous battle conducted by the Duke of Wellington to convey the results of the military engagement. By creating the impression that the battle had been won by the French, he bought government bonds at a sharp discount in the ensuing market panic to which he had contributed. This early success formed the basis of his personal fortune, which was estimated on his death to be worth $100 million in present day dollar values. His private wealth allowed Ricardo to retire early and to engage in his scientific interests. He became attracted to the study of economics as a result of reading Adam Smith's *The Wealth of Nations* (1776) while on vacation in the English resort of Bath in 1799. Ricardo began to write influential articles about the pressing economic matters of the day such as the corn trade and became acquainted in 1811, with such influential figures as Jeremy Bentham and James Mill. He engaged a lengthy correspondence with Thomas Malthus over the role of the landowning class in British society. He achieved prominence as a member of several influential London clubs such as the Political Economy Club, the King's Club, and the Geological Society. These social connections were important in his entry into Parliament in 1818 through purchasing the borough of Lord Portarlington for 4000 sterling. Ricardo died at Gatcombe Park, Gloucestershire, at 51 years of age from an ear infection that resulted in septicemia. Buried at St Nicholas Churchyard Chippenham, Wiltshire, he never lived to see the 1836 Repeal of the Corn Laws, which was a vindication of his pamphleteering for free trade, and he did not live to witness Ireland's great famine of the 1840s with its brutal confirmation of the laws of the free market.

Among the educated public only a few names stand out in the history of economic thought. These are Adam Smith, the spokesman for individualism and competitive capitalism; Robert Malthus, who earned for economics the title of 'the dismal science' from Thomas Carlyle in 1849, by virtue of his belief that any temporary gain in well-being would be undermined as a consequence of inducing a population explosion that would entail diminishing returns and a retreat back to a subsistence ration of real wages; Karl Marx, the prophet of capitalist crises and the exponent of allegedly scientific socialism; John Maynard Keynes, proponent of the mixed economy, who rescued capitalism from the post-1929 Great Depression and designed Britain's postwar recovery by interventionist governmental macroeconomic policies and public regulation. The classical political economy of Malthus and Ricardo is often associated with the idea of negative unintended consequences of action. Both men were criticized by Albert O. Hirschman for their 'rhetoric of reaction' or the 'perversity thesis,' namely "any purposive action to improve some feature of the political, social, or economic order only serves to exacerbate the condition one wishes to remedy" (Hirschman, 1991: 7). For example, raising the wages of the working class would be self-defeating, because it would increase the fertility rate of the poor resulting eventually in more poverty.

Within the economics profession, Ricardo has now achieved a prominent status, but in the past he was not always respected and recognized. In his *History of Economic Analysis*, Joseph A. Schumpeter (1954) coined the phrase 'the Ricardian vice' to describe how Ricardo piled up arguments to hide his confusion of facts and values. He also complained that Ricardo had failed to make any real progress in the development of a general equilibrium model. Among twentieth-century economists perhaps the most important tribute to Ricardo came from Paul A. Samuelson (1969), who was once challenged by Stanislaw Ulam the Polish mathematician, to name any nontrivial universal law in the social sciences. After some reflection, Samuelson claimed that it was Ricardo's analysis of 'comparative advantage,' which stated that to achieve successful development a society should not attempt to focus on a range of diverse productive activities, but only on those economic activities that gave them a comparative advantage in international trade.

In retrospect we can now see him as the archetypical classical economist, the economist's economist who supposedly improved upon Smith and spelled out with Euclidean logic the eternal behavior of the market system. In an amiable exchange of letters with Malthus, Ricardo was undoubtedly the outright winner, because Malthusian fears of recurrent depression stemming from underconsumption spending were argued to be fallacies. The self-made millionaire David Ricardo captured the respect of the Victorian devotees to *laissez-faire* as well as socialistic critics of Marxian or romantic stripe. He has recently received an excellent if somewhat overdue full-scale biography (King, 2013).

Ricardo was also fortunate in having Piero Sraffa edit for the Royal Economic Society, over a period of 25 years, a magnificent and complete edition in 11 volumes of *The Works and Correspondence of David Ricardo* (1951–73). Although this collection revived interest in Ricardo's economic thought, oddly it seems to have contributed to a revisionist erosion of his analytic reputation. Whereas the late-Victorian Alfred Marshall, pillar of post-1870 neoclassicism, had idiosyncratically argued that the good modern stuff was *already* in Ricardo, and whereas Keynes had written in the 1920s that Ricardo had 'the finest mind that had come to economics' – neither Ricardo's late twentieth-century admirers nor detractors could agree among themselves as to what his different virtues and vices actually were. A scholar who is much misunderstood cannot be acquitted of all responsibility for ambiguity.

Reversing the usual order of intellectual progress, Ricardo first made his mark in what has come to be called *macroeconomics*. His unqualified verdict typifies his noneclectic style. To finance a very long war against Napoleon, Britain expanded its money supply of paper currency in order to procure goods at home and abroad for its armies. Price-level inflation was unsurprisingly part of the economic history in that period. The eclectic theory of Adam Smith would no doubt have predicted as well a worsening of terms of trade as Britain and other belligerents bid up the relative prices of needed imports. Had gold and silver been the sole money used then in Britain and elsewhere, the 1750 theories of David Hume would have predicted a drain of specie from London to pay for the war-induced trade deficit of exports compared to imports.

However, even in those distant times much of the money employed for purchase and sale transactions involved the use of paper money currency. As is customary in times of war, whatever the supply of domestic gold or silver, there ensued a considerable rotation of the printing press to finance government needs and accommodate the desire for the enhanced cash necessary to conduct the enlarged volume of goods transactions and their higher average prices. Under these circumstances, whenever a government chooses *not* to redeem paper currency notes into specie at their previous face value, those notes will depreciate in price relative to ounces of specie. The high price of gold is what the person in the street calls this phenomenon and there was considerable controversy as to its causes. Ricardo attributed *all* of the rise in gold prices to overissue of paper notes.

Today one can entertain counterfactual history. Somehow the British government might have taxed the populace more heavily to finance the enhanced war effort and maintain a balanced budget and the inescapable rise in relative import prices. As a general strategy the government could have imposed tightness in bank lending, enforceable only at higher interest rates, and conceivably could have kept the stock of paper currency unchanged. The outcomes would almost certainly have included higher unemployment and extra loss of consumption on the civilian populace. With heroic tightness, trade balances might even have been forced to cancel out to zero. It is hard to envisage how normal peacetime unemployment levels could have somehow been made to prevail from say 1795 to 1810 in this counterfactual scenario. An inflation-free war can thus be painfully conjured up in counterfactual history and with no wartime increment of paper currency issue.

In actual history, paper notes depreciated and price levels soared. As happened a century later, during the 1920–23, German hyperinflation, economists held opposing views of appropriate economic policies. Ricardo argued that overissue in currency M explained virtually *all* of the rise in the price of bullion. Henry Thornton, practical banker and Bank of England authority (at first), argued that the microeconomic phenomena of adverse trade balances and war-induced buoyant business activity explained a significant fraction of the observed appreciation of bullion. Ricardo's 1809–10 strong assertion of what was called the 'bullionist view' won him instant celebrity, particularly with the dogmatic James Mill. But this economic debate was not really a zero-sum game in which Ricardo's gain had to equal Thornton's loss. Both men agreed on the likely longest-run outlook. The price of gold in terms of paper would be the same in 1850 if, in the many preceding decades, the supply of paper currency was limited enough to permit free specie–currency convertibility at the old 1790 ratio. In this instance, the so-called 'Ricardian vice' was his use of *long-run* true relations to characterize actual short-run patterns in economic history.

After the first decade of the nineteenth century, Ricardo concentrated mostly on *microeconomics*. In 1815 (and *not* prior to then), along with Malthus and Edward West he helped to articulate the 'law of diminishing returns' and its consequences for land rent determination. Society's product, for example, corn, is produced by labor and by land, both working together. When you increase labor in two *equal* increments, working on fixed land, you acquire two successive increments of corn. But

the second gain is presumptively *less* than the first – a technological law of nature. Thus the wage that the competitive market can pay to labor goes down when labor/land density increases, and the rent that the market will pay for land will go up. This is not a new idea – it is in Benjamin Franklin (1755) early in the eighteenth century and already in Smith (1776) – but it is an important insight that needed to be made explicit.

Already Ricardo had perceived what he considered faults in Adam Smith. Posterity can be grateful that this perception tempted Ricardo into economics, even though it can be argued convincingly that Smith was mostly correct in the cases where Ricardo criticized him. For example, in the capital-and-land-and-produced-capital models that both writers worked with, Smith was right to jettison the 'labor theory of value' as soon as either the interest rate and/or the land rent rate becomes significantly positive.

As between the two tasks of political economy – (1) understanding how relative scarcities of factors of production constrain the alternative availabilities of different goods and their valuation relations; and (2) how society's harvest gets *distributed* among and between the different social classes of workers and owners of property – Ricardo arbitrarily declared it was distribution that was all important. Yet nowhere in the 11 volumes of his *Works and Correspondence* (1951–73) will the reader find a *complete* and satisfactory theory of distribution that went beyond what was already in Smith, Malthus, Mill, or modern mainstream writers.

Perhaps the lack of a university education contributed to Ricardo's methodological style. Frequently, he asserted general 'truths' that admit of important exceptions; repeatedly he failed to distinguish between *necessary* and *sufficient* conditions for an argument. He was a superb miniaturist but with an absence of coherence, particularly in his post-1815 textbook phase. Ricardo's theory of comparative advantage in international trade, similar to that of the contemporary Colonel Robert Torrens, is a brilliant example of his miniaturist virtuosity.

Perhaps with hindsight, this is a somewhat harsh judgment on 1810–23 David Ricardo, but one can be even harsher on Ricardo's twentieth-century commentators. The brightest and the best of them – Piero Sraffa, George Stigler, Samuel Hollander, Mark Blaug, and scores of others – while understanding that the positive interest and time-phasing of production generically invalidate Ricardo's championing of the *labor theory of value* (as, indeed, Ricardo himself intermittently admitted), at the same time they appear blind to the parallel fact that positive rent(s) on scarce land(s) must similarly invalidate the labor theory of value. Edwin Cannan, Knut Wicksell, Jacob Viner, and Lionel Robbins are exceptions to this general criticism about how labor/land intensities generically invalidate any labor theory of value in the same logical way that time intensities are known to do so.

Around 1815, between his macroeconomic works on gold and his *Principles of Political Economy and Taxation* (1817, 1819, 1821), Ricardo puzzled over a simple scenario involving a farm good (corn) and one or more manufactured goods (cloth and other products), all produced by, say, homogeneous labor, homogeneous land, and by one or more *produced* inputs (corn seed, raw materials from farming used for manufactures, and durable tools). He may even have worked out, in an unpublished manuscript that has not survived, a one-sector farm-only model. A determinate model of distribution could have cogently defined a long-run stationary-state equilibrium for (real corn wage rate, interest rate, real corn rent rate) = ($W/P_{\text{corn}} = \bar{w}, \bar{r}$, Rent$/P_{\text{corn}} = R^*$). How would it have gone?

Like Malthus and other predecessors, Ricardo would have specified *ex*ogenously a classical 'subsistence wage' rate, $\bar{w}$, needed to keep population just reproducing itself. Like his classical successors Ricardo would have specified *ex*ogenously a minimal interest rate, $\bar{r}$, needed to keep capital(s) just reproducing themselves. Land being a classical constant, $\bar{A}$, its stationary equilibrium rent rate he would *residually* determine once variable labor-and-capital stocks, L_t and K_t, dynamically converged to their long-run, asymptotic stationary equilibrium levels: $L_t \to L^*$; $K_t \to K^*$, when K is a single scalar. Finally, short-run determination of w_t and r_t would be market-clearing rates dependent on the relative transitional abundances of L_t and K_t.

Here is how in the spirit of Prokofiev's 'Classical' Symphony, an ambitious neophyte in a 1932 Hicks–Wicksell *neo*classical workshop might synthesize these classical insights into a coherent simplistic dynamic equation system, using the notational convention $dY_t/dt = \dot{Y}_t$:

$$\begin{aligned} \text{Factor supplies}: \dot{L}_t/L_t &= |\bar{\alpha}|\varepsilon(w_t - \bar{w}) \\ \dot{K}_t/K_t &= |\bar{\beta}|(r_t - \bar{r}), A_t \equiv \bar{A} = 1 \end{aligned} \qquad [1]$$

$$\begin{aligned} \text{Factor demands}: w_t &= \bar{\sigma}K_t^{1/3}/L^{2/3} \\ r_t &= \bar{\sigma}L_t^{1/3}/K_t^{2/3} \end{aligned} \qquad [2]$$

where $\bar{\sigma}$ is an exogenous parameter denoting level of technical productivity.

When the modern crank of deduction gets turned, Ricardo's [1] and [2] do lead convergently to a determinate classical stationary state. From any *initial* $(L_0\ K_0\ \bar{A})_0$, as $t \to \infty$,

$$\begin{aligned} &(w_t, r_t; L_t/\bar{A}, K_t/\bar{A}; R_t) \\ &\to \left(\bar{w}, \bar{r}; \frac{1}{3}\bar{\sigma}\Big/\left[\bar{w}^2\bar{r}\right], \frac{1}{3}\bar{\sigma}\Big/\left[\bar{r}^2\bar{w}\right]; \frac{1}{3}\bar{\sigma}[rw]\right). \end{aligned} \qquad [3]$$

One must commend the classical tradition for so subtle an accomplishment. The version worked out here differs from Paul Samuelson's 'canonical' model, which had more faithfully adhered to the conventional labor-capital 'dose' version (Samuelson, 1978).

This above supply–demand equilibrium is definitely *not* independent of the problem of how consumers wish to allocate their earned incomes among the many goods, when there are many noncorn goods in the market. Then there are no 'natural prices' definable independently of how consumers choose to spend their incomes.

Definitely goods' relative price ratios do not remain close to proportionality with their respective embodied labor contents, $P^i{}_t/P^j{}_t \neq (L^i{}_t/q^i{}_t)/(L^j/q^j{}_t)$. Likewise embodied land contents $(A^i{}_t/q^i{}_t)/(A^j{}_t/q^j{}_t)$ and embodied capital contents $(K^i{}_t/q^i{}_t)/(K^j{}_t/q^j{}_t)$ similarly fail as approximations to empirical actual P^i/P^j ratios.

Since Ricardo did not coherently understand the intricacies of his own classical scenario, he never realized how

unattainable was his hankering to have all relative prices determinable purely *by objective technology and cost data*. Subjective variabilities (1) of consumers' utilities and demand choices, and (2) of intertemporal saving-and-consuming choices – which became central preoccupations of post-1870 neoclassical thinkers to the classical school – were thus *already* unavoidable in the capital, land, and labor models of classical theory and in the competitive scenarios that Marx grappled with all his working life. This inevitability will come with pain for the small sect of Sraffian neo-Ricardians who proliferated after 1925 and especially 1960.

Ricardo was low keyed and civil in argumentation, albeit firm in holding to his strong positions. The letters between Ricardo and Malthus, notwithstanding their obvious differences, were a model of courtesy and affection. Despite Ricardo's typical unqualified dicta, he did not hesitate to change his mind and admit to previous mistakes. Marx, who abhorred classical authorities and for whom 'Parson' Malthus was a particular *bête noir*, was uncharacteristically soft toward Ricardo. Here is an illustrative incident. After the first edition of *Principles*, but prior to its third edition, Ricardo had declared that technical invention *must always* help *all* factors of production, including the working man. He encouraged disciples, like J.R. McCulloch, to affirm this strong view. However, on reconsideration, Ricardo came to realize that some inventions can assuredly *replace labor and reduce the demand for labor in the short and the long run*. Therefore, despite warnings from his friends that this position would weaken the case for *laissez-faire*, Ricardo added a new chapter on Machinery to the third (1820) edition of the *Principles*, presenting exposition and numerical examples designed to show how labor's share of national income could suffer from certain possible inventions and how long-run equilibrium populations and gross income levels could be permanently lowered. With virtually no exceptions, ancient- and twentieth-century authorities agreed that for once Homer had nodded. For once Ricardo must have invoked rigidity of wage rates with its resulting unemployment, thus for once denying J.-B. Say's sacred dogma that overproduction is impossible in a capitalist system. Karl Marx praised the scholar for his honesty.

It is a story that casts discredit on virtually all. The Ricardo–McCulloch original sweeping position was gratuitously wrong. A new wind that raises an economy's potential for production and consumption most certainly can do harm to *some* competitors while helping others. Ricardo did not claim, as J.S. Mill and Vilfredo Pareto were to argue subsequently, that gainers could always bribe losers so that *with intervention all could gain*. Nor did Ricardo's new understanding motivate him to abandon a dogmatic defense of *laissez-faire*. His critics on Machinery, both then and in our time – including Knut Wicksell, Nicholas Kaldor, Joseph Schumpeter, and George Stigler – failed to see the absence in Ricardo's exposition of any denial of dogmatic Say's Law and its ruling out theoretical harm from underconsumption. Instead his usual classical scenario of population decline dictated by the induced drop in the wage below an alleged equilibrium *subsistence* rate would, as the Machinery chapter alleged, call for an ultimate drop in population and gross product as a result of labor-saving invention(s). Just as the Industrial Revolution was beginning to raise wages by a genuine filter-down process, the armchair philosophers were getting their first intimations of the complexity of how a market system hands out its distributive awards.

In summary, David Ricardo, like the twentieth-century economists Friedrich Hayek and Milton Friedman, importantly pushed voters and public opinion toward libertarian *laissez-faire*. Victorian England's Whig society and Manchester School owed much to him. In the modern debate about how a modern mixed economy can optimally compromise between market mechanisms and democratic rules of conduct, Adam Smith and John Stuart Mill appear to be more subtle classical thinkers. From these two, autocratic rulers like Lenin, Stalin, and Mao could have had much to learn. But among the worldly philosophers, David Ricardo must be counted as an important influence on the formation of the twenty-first-century mind.

While Ricardo's status among classical economists is secure, he has not received sufficient attention from sociologists. Ricardo developed the basis of a theory of social classes before Karl Marx's class conflict theory and before Max Weber (1978) had developed his famous model of 'class, status, and power.' There were important social classes in Ricardo's work – the working class who depend on wages, the landowning class who extract rent, and the bourgeoisie who exploit the labor of the workers to create profit. Ricardo had been especially critical of 'Old Corruption,' namely the ability of the rent-seeking aristocracy to dominate Parliament in their own narrow interests.

In classical sociology, Marx argued that with the maturation of capitalist society there would be a class polarization and two dominant classes would appear – the proletariat and the bourgeoisie – as the driving force of history. Barrington Moore (1966) in *The Social Origins of Dictatorship and Democracy* provided a more complex comparative analysis more consist with Ricardo in which democracy required a thriving bourgeois class, while authoritarian regimes are the product of a weak bourgeoisie and an alliance between the peasantry and aristocratic landowning class such as the Junkers in Germany. He advanced the slogan – 'No bourgeoisie, no democracy.' Advanced capitalist societies are no longer so obviously stratified into social classes that exert collective political influence, and some sociologists argue that, following Ricardo, the technological revolutions of the twentieth century have brought about some de-skilling of the workforce leading to an erosion of the political clout of the working class (Braverman, 1974). Modern societies are instead characterized less by class conflict and more by growing income inequality and the hollowing out of the middle class (Krugman, 2003). These sociological debates indicate that Ricardo should be regarded as a founder of modern sociology as well as of classical political economy.

Abstract

Paul Ricoeur (1913–2005) was an eminent French philosopher working at the crossroads of many schools of thought (hermeneutics, phenomenology, analytical philosophy, etc.) and in constant dialogue with the human sciences. He taught mainly in France and the United States, and gained international recognition after the publication of *Oneself as Another* in the early 1990s. This book is emblematic of Ricoeur's broader work in the way it binds existence and interpretation through language, culture, and interactions with others. Ricoeur proposed a practical approach to what he called 'meaningful action,' which is open to different and often conflicting readings. For him, meanings are not ascribed once and for all, but must be constantly negotiated and experienced as such. This also holds true for politics and ethics, as Ricoeur reworked the ancient notion of *phronesis*.

Life and Career

Paul Ricoeur was born on 27 February 1913 in Valence, France. While the World War I was a difficult ordeal for everyone across Europe, it was a particularly troubling experience for the young Paul: his mother died few months after he was born, and his father died during the Battle of the Marne in September 1914. Orphaned and considered wards of the state, he and his sister were brought to Rennes to be raised by their paternal grandparents and an unmarried aunt. It was during the 1930s that Ricoeur discovered philosophy, first under the influence of Roland Dalbiez and then in a more robust study program in Rennes and Paris, where he encountered many important philosophical figures of that time, including Gabriel Marcel. In 1935, he married Simone Lejas, and they went on to have five children together. (Biographical details of Ricoeur's life and career are taken from the following sources in English and French: Dosse (2008), Greich (2001), Hahn (1994), and Kaplan (2008).)

Ricoeur was drafted into the French army in 1940; he went to the battlefield for a very short time before being captured. He then spent 5 long years in captivity during which his only consolation were his fellow prisoners, including a diverse array of philosophers: Mikel Dufrenne (with whom he later published a book on Karl Jaspers), Roger Ikor, Jacques Desbiez, etc. It was also in these rather uncomfortable circumstances that Ricoeur worked on the French translation of Husserl's *Ideen I*, which was published in 1950.

After the war, Ricoeur finished his dissertation, published some papers, and began his academic career, first at Strasbourg (1948–57), then the Sorbonne (1957–64), and later at Nanterre (1965–70). A respected professor, he was keen to engage, sometimes critically, with fellow scholars from other disciplines, especially the human sciences in general, and structuralism in particular. His debate with Claude Lévi-Strauss, for example, in the journal *Esprit* (1963) is symptomatic of this, even though Ricoeur had little chance of challenging the then extremely fashionable intellectual trend on *la rive gauche*; indeed, his criticism of structuralism garnered much of his own criticism, some of which more personal than theoretically grounded.

The late 1960s was yet another time of turmoil in the Western world, and in Ricoeur's life. The student protests of May 1968 were particularly intense in Nanterre, where Ricoeur acted briefly as dean and was incapable of restoring order on campus. He finally resigned from that position in March 1970, which also marked a period of relative withdrawal from French intellectual life.

Ricoeur's international career took off in the 1970s through different conferences and teaching assignments (at Louvain, Columbia, and Yale, for instance). But it was in the American Midwest that Ricoeur would primarily make his home, as he succeeded Paul Tillich as the John Nuveen professor of philosophical theology at the Divinity School of the University of Chicago, with a joint appointment in the philosophy department (1970–92). Such an environment proved to be extremely fruitful: both Hannah Arendt and Mircea Eliade also worked there at that time, and Ricoeur managed to write his highly influential books *The Rule of Metaphor* (1975) and the three-volume *Time and Narrative* (1983–85).

The next decade or so signaled a return to the French intellectual scene for Ricoeur, as well as his inclusion among the most preeminent philosophers of the century. While the publication in 1986 of *From Text to Action* can be considered an important step in this process, the most exposure came with *Oneself as Another* in 1990. At that point, Ricoeur had been working for more than 50 years, and this book is generally considered to be emblematic of his mature thought.

Reflecting his profound and personal dedication to philosophy, Ricoeur continued working into the 2000s, publishing several books including *Memory, History, Forgetting* (2000). He passed away on 20 May 2005. In his prolific career, he received over 30 honorary degrees, many of which from highly distinguished institutions such as Northwestern (1977), Göttingen (1987), and McGill (1992). He also received multiple awards such as the French Academy's Grand Prize for Philosophy (1991), the Balzan Prize (1999), and the John W. Kluge Prize in the Human Sciences (2004).

Ricoeur's Work as Dialogue and Translation

Such a prolific career as Ricoeur's inevitably raises the question of what constitutes its unity, or, similarly, what could be its *modus operandi*? As mentioned above, Ricoeur often engaged over the years with the human sciences and indeed, this 'step outside of philosophy' could be considered a guiding thread of his work (see Ricoeur, 1977; for instance; for commentary, see McGuire, 1981; and Moore, 1990). His is a thought rooted in dialogue, open to dialogue, striving for dialogue. By turns, Ricoeur referenced world events and engaged with other disciplines, intellectual currents, and traditions – be they from French, German, or Anglo-American universities. In each of his books, he developed what, following Jaspers, he called 'loving struggles' with different authors, aiming at better self-understanding.

In 2004, for instance, he published a small yet dense book called *On Translation*, which not only tackles important questions about the current state of globalization, but also retrospectively applies to his own academic journey (see Jervolino, 2008). In it, he asks fundamental questions: What does it mean to translate? What kind of possibilities does it open up? According to Ricoeur, the act of translating is one by which the translator accepts the uniqueness of the original text while simultaneously affirming that it can be otherwise communicated. The goal is to stay true to the original meaning; but even though the perfect translation does not exist, this does not mean that all efforts are made in vain. To translate is to engage in an act of meaning-making informed by a close and patient reading of something that precedes it. It is to accept both the capacities and the limitations inherent in the art of interpretation. Indeed, Ricoeur's hermeneutics never ceases to deal with this issue; in that sense, it is concurrently a method, a philosophical project, and an overall way to read the world.

This particular alliance between the individual, meaning, and interpretation runs exceptionally deep throughout Ricoeur's work. It is a conceptual articulation that informs his early philosophical anthropology and also proves central in his later ontological developments. Books such as *The Voluntary and the Involuntary* (1950) and *Fallible Man* (1960), for instance, explore these themes, especially the constitutive disproportion of the human experience and the opacity of the cogito. Our embodied lives and the fact that the world always precedes us generate a finite situation with an infinite task: the desire to express and understand ourselves. "The ultimate root of our problem," notes Ricoeur, "lies in this primitive connection between the act of existing and the signs we deploy in our work; reflection must become interpretation because I cannot grasp the act of existing except in the signs scattered in the world" (1965/1970: 46). But the problem is the solution, and vice versa: meaning and culture are both a long and complicated detour around being, as well as the only resource for a cogito that cannot have direct access to itself, *à la* Descartes.

The question of what constitutes a symbol arises from this delicate connection between existence and interpretation, which Ricoeur explores in depth in the *Symbolism of Evil* (1960). In this work, he looks at different backgrounds and cultures, all of which have tried to come to terms with evil by devising myths and stories to make sense of both evil's origin and its end. Symbols – Eve, the snake, and the apple in the Bible, for instance – operate at the junction between two types of meaning: the literal and mundane on one side, and the figurative and spiritual on the other. There is thus a double sense to all symbols; they are in a constant state of polysemy. But for Ricoeur, they 'give rise to thought' precisely for this reason, as they propose a 'surplus of meaning' that has to be decoded and appropriated by individuals.

Gradually, however, it is the notion of text that would become the central feature of Ricoeur's hermeneutical approach. The two main forms of language, speech and text, are fundamentally different, as the latter introduces a significant distance into human communication. A text has an internal logic that creates an inner structure, which in turn allows for a certain closure or autonomy. This can also be thought of in terms of semiotics, and Ricoeur would use this concept to engage with the structuralists of his time, Lévi-Strauss most prominent among them. But a text is more than just its own architecture of signs; it wants to express something, which makes it a semantic entity unto itself. It refers to a projected world and thus to "understand a text is to follow its movement from sense to reference, […] from what it says, to what it talks about" (1976: 87–88). The world of the text is our world, i.e., it deals with human experience in such a fashion that it creates something like a *Lebenswelt* – a living world that the reader is able to relate to.

Ricoeur's pivotal notion of text thus connects semiotics and semantics, explanation and understanding, more than it separates them. For him, as well, textual exegesis must be rigorous; there is a validation procedure that should be applied, such that "it is not true that all interpretations are equal [… as the text] is a limited field of possible constructions" (1986/1991: 160). This holds true for the text's reference, if one accepts that it deals with the social field of human action. In a seminal essay entitled "The Model of the Text: Meaningful Action Considered as a Text," Ricoeur develops four analogies that militates for the objectification of the practical field. First, while meaning surpasses its occurrence, what constitutes the significance of an act goes beyond the simple fact that it happened. Second, the propositional content of an act or a text, as much as its illocutionary force, points toward a "logical status as having such-and such identifiable meaning or 'sense-content'" (1981: 205) – saying 'I do' at a wedding, for example. Third, and because of what precedes, the meaning of an act can detach itself from the will of its agents and produce its own outcomes. And last but not least, actions or texts can be interpreted by a wide range of readers, present and future, who propose different interpretations and argue for their relative merits, like the social sciences would do, for instance.

Over the years, and especially in the 1980s and 1990s, this hermeneutics of text and action produced a remnant, a questioning that for Ricoeur had to be transformed or translated. He was also growing unsatisfied with his treatment of the self and its capacities. In books like *Time and Narrative* and *Oneself as Another*, he explored the fragile human condition by focusing on two themes: identity and temporality. What is it to maintain the self through constant change and evolution, or even the simple fact that people age? In asking how to answer the question 'who?' Ricoeur's response is to build on a distinction

in Latin between *idem* and *ipse*. To stay the course, to persist unchanged in one character is to promote a sort of tautology, an *idem*-same, or self-same. On the contrary, through *ipseity* one would accept and welcome changes, understanding the unity of his life in analogous terms and thus the self as *comprised* of its different actions. For Ricoeur, in other words, what is fundamental for the self is to be *like* the author of his own life and to be recognizable as such.

The development of such a hermeneutics of the self necessarily involved the use of language, and Ricoeur insisted on the narrative construction of the self and thus developed the concept of 'narrative identity.' Meaning-making goes hand in hand with storytelling, and through this process a person becomes a persona, while his life is both a work in progress and an emplotment. "It is the identity of the story," notes Ricoeur, "that makes the identity of the character" (1990/1992: 148). And this, in turn, also implicates other people and other personae: the language of the self is a form of dialogue insofar as action is always a form of *interaction*. Ricoeur's interpretation is rather innovative as it allows for connections with both the social sciences and ethics. The key here is 'recognition,' which becomes more obvious in later books such as *The Course of Recognition* (2005), and emerges as mutuality, social esteem or even as a promise. For example, "I promise that in the future I will respect what I say now; I will be true to my words, to myself, and—especially—to you."

It is by way of analogy and translation, once again, that this relationship between alter and ego allowed Ricoeur to speak more generally about history, society, culture, and politics. From two individuals, to three and beyond, up to the creation of institutions, there is both continuity and rupture. The advent of institutions – what Husserl called 'personality of the higher order' and Weber 'groups of domination' – signals in effect a certain crystallization of human action, the creation of an order or a structure. These exist to achieve goals and make difficult collective decisions, but precisely because of this function, they can also introduce forms of coercion. Therein lies their fragility, or what Ricoeur in 1957 named the 'paradox of politics,' in reference to the events that had recently occurred in Prague. Simply put, rulers demand more authority and control than the ruled are willing to give them.

If the use of force has proven to be constant throughout history, the same can be said about the many justifications made by political entrepreneurs, in terms of rhetoric and ideology. Broadly speaking, this is where politics meets interpretation and culture: "Ideology is a function of the distance that separates the social meaning from the inaugural event which must nevertheless be repeated" (1981: 225). In other words, no group can reproduce its identity without narrating its origins, and yet this ongoing narrative process hides as much as it reveals, as ideology inherently introduces ambivalence and distortion.

For Ricoeur, the fundamental question with regards to politics is not truth per se, but rather what constitutes legitimacy. Politics is rooted in language and triggered by conflict: conflicts of interpretation, conflicts of power and interests, etc. The question, time and again, is what *should* people do? What is acceptable? What kind of agreement can be reached? What can be considered fair treatment? Ricoeur held that democracy is fundamentally informed by these equivocal questions. Ambiguity, in other words, is the necessary condition for deliberation and participation. To engage and to argue is an endless task to be sure, but it is this sort of collective work that shapes and maintains healthy citizenship. Ricoeur's analysis, through this latest question, begins to demonstrate some of its ethical importance. For instance, in response to the ultimate question of what constitutes justice, he would plead for less inequality and more overall social inclusion. Justice, then, is the horizon. In *Oneself as Another*, he offers a succinct expression that summarizes his thought, stating the goal is to be "with and for others in just institutions" (1990/1992: 262).

Justice is to politics what the 'good life' is to ethics. For Ricoeur, these two *telos* or aims are intimately linked. They share a common undecidability and, because of this, must be experienced in a practical way, i.e., through action and language. Following Aristotle's notion of *phronesis*, Ricoeur insists on the many differences between such practical wisdom and what could be considered a more robust understanding of morality built from the reinforcement of norms and obligations. From this, it follows that the road toward the good life has flexible guidelines, among which three are of greater interest. First, according to Ricoeur, the idea that the other shall be respected both as capable and fragile – the theme of the 'Fallible Man' is present here – informs a solicitude for which the other is an end in itself and never a means. Second, as I recognize the uniqueness of other individuals, I also recognize my own uniqueness. Consequently, I myself am an agent and shall be held accountable for my actions. Third, as the self tries to be respectful and responsible, he finds himself immersed in a never-ending process of reflection, such that the good life is and remains only an interpretation. For Ricoeur, however, this is not a flaw, but an extraordinary resource, something that helps us make sense of the most difficult questions. With the help of reflection, doubts are introduced that both allow us to reassess and reaffirm our convictions.

Ricoeur's Legacy

2013 would have marked Ricoeur's 100th birthday, and in his honor several conferences were organized and commemorative publications were produced. Together, these efforts have reinforced Ricoeur's position as a leading figure in contemporary philosophy, a continuation of the accolades and respect he received throughout his career. Even more significant in this regard, however, is the creation in 2010 of the *Fonds Ricoeur* in Paris, a project that acts as a focal point, a *passage obligé*, for all scholars who want to study his work in depth. All of Ricoeur's archives can be found there, along with his personal library. The devoted group who maintains the *Fonds* makes sure that everything published on the philosopher is properly acknowledged; they are also aiming to build an international scholarly network that includes the Society for Ricoeur Studies and a Web journal entitled *Etudes Ricoeuriennes/Ricoeur Studies*. Thus, it is quite possible today to say that the work has not only survived the death of its author, but that it has acquired a life of its own. Its finitude continues to open plural interpretations and, in that sense, the work still fundamentally concerns dialogue and translation.

Another and perhaps broader way to assess Ricoeur's legacy is by examining the scope of his work. Is it vast enough to

be more than just a collection of disparate moments and intellectual topics? Does it point toward a form of universal hermeneutics or is it more local and specific? To what extent, in short, is it systematic? These questions are perhaps best addressed by measuring the distance separating Ricoeur's work from Hegel's dialectic, which strives toward synthesis through Reason. 'Renouncing Hegel,' in fact, is the title of an important chapter of *Time and Narrative*, in which Ricoeur is insistent in his critique of Idealism; while meanings are complicated and plural, they are more ambiguous than logical and rational, as they are for Hegel. This also implies that it is always difficult to resolve practical or social conflict and, ultimately, that political powers, especially states, cannot be understood as a source of more than justification. The links between social and political conflicts and conflicts of interpretation are, to be sure, both constant and robust in Ricoeur's work; the dialogue among them is essentially what replaces Hegel's dialectic. Furthermore, this allows for a connection between the universal and specific aspects of hermeneutics. It is not mandatory to choose one over the other, for both aspects cohabitate and find a rare and interesting balance in Ricoeur's work.

Similarly, such a balance can be seen in Ricoeur's negotiation between philosophy and the human sciences. This conversation is at the same time peripheral and central; and again, there is no need to choose one over the other. Ricoeur engaged with the human sciences beginning in the 1960s and continued to do so up until the very end of his career, receiving many insights and offering many of his own, as well. Indeed, it is possible to argue that his work is a philosophy *of* the human sciences, or *in* the human sciences; his work can vitally inform their epistemological foundations, the realities they face, and their ethical horizons. And this explains why Ricoeur's dialogue with the human sciences is so important. Who makes this kind of effort nowadays? Who is trying to make such important connections among these disciplines? The present era is more geared toward specialization, even hyper-specialization, and because of funding requirements and institutional retrenchment, philosophy and the human sciences have tended to drift further apart. Ricoeur's most important legacy, then, is the crucial reminder that it is still possible to do otherwise.

Abstract

David Riesman became famous because of his 1950 bestseller *The Lonely Crowd*. Before that he received his education at Harvard and was a professor of law at Buffalo and of social sciences in the College of the University of Chicago. Later, he returned to Harvard. Besides his devotion to teaching, he acted as a public intellectual during his lifetime. In the *Lonely Crowd* study, he proposed the change of social character from tradition-directed, to inner-directed, and then to other-directed. This heavily value-laden concept helped make the book one of the rare examples of a social science bestseller. Whereas an inner-directed person follows the instruction one picked up early in one's life, the other-directed person orients his behavior according to the cues he gleans from his peers and the prevailing mass culture. Riesman later on abandoned his own characterology but he continued to be concerned about changes in society and politics. His less-known publications on higher education demonstrate his familiarity with the world of undergraduate education in the United States and show his incorruptible personality vis-à-vis cultural pressures.

Like many others from his generation, David Riesman chose sociology because he thought the knowledge developed in this discipline might help not only to understand the present time but also to change it. More than many others, Riesman enjoyed real influence in his time and much beyond his own sociocultural environment. Looking at him and his *oeuvre* from a present viewpoint, even an unprejudiced observer would not file him and his writings under 'sociology'; at least they do not fit into the contours of that discipline as it is today. The sociology Riesman discovered in the aftermath of the World War II was quite different. Riesman questioned whether this obvious change was to the better of the discipline. After Riesman's death, one of his numerous friends, collaborators, and admirers published an op-ed essay on him and his legacy in the *New York Times*. He titled it 'The last sociologist' (Patterson, 2002). True or not, Riesman was a sociologist of a particular shape.

Apprenticeship Years

Riesman was born in Philadelphia in 1909 into a wealthy family of German-Jewish origin. His father was a professor of medicine at the University of Pennsylvania and his mother a college graduate with a broad spectrum of interests. Their son, David Jr., showed similarly broad interests as early as in high school. He thought first to follow his father's path and become a doctor too. At college, he majored therefore in biochemistry, but the college was Harvard with its wide spectrum of digressions, several of which Riesman took. He became an editor of the student newspaper, *The Harvard Crimson*, where he collaborated with, besides many others, the later Marxist scholar and economist Paul Sweezy (Riesman, 1990: 29, 45). Riesman later wrote that the *Crimson* was his 'major educative enterprise' and that the curriculum bored him (Riesman, 1953). In one of his autobiographical essays, he admitted that at this time, he accepted his mother's definition of him as an 'uncreative,' so his next decision might have been seen by his mother as a proof of her opinion (Riesman, 1988: 3). He graduated in 1931 and at this time his interests had changed to a complete different field, law. He chose the Law School 'aimless' but with a clear agenda to remain near his new found mentor, Carl J. Friedrich, whose friendship lasted for the rest of their lives. Friedrich, 9 years older than Riesman, was a quite recent immigrant from Germany, and held a position in the Department of Government. Riesman admired him both for his erudition and encouragement and later claimed that he "owe[d his] introduction to the social sciences to Friedrich" (Riesman, 1988). Riesman must have possessed a particular brightness that his mother might have overlooked because in his second year as a graduate student he was recruited to the group of editors of the *Harvard Law Review*. For more than a decade, Riesman pursued law. After graduation, the eminent member of the Law School and future Supreme Court Justice, Felix Frankfurter, tried to channel Riesman into academic work, something the young man resisted for a while. Instead, he took up the private practice of law. In between Riesman served 1 year as a law clerk to U.S. Supreme Court Justice Louis D. Brandeis. The young man started an argument during the hiring conversations by calling Zionism a Jewish fascism, probably because Brandeis's sternness reminded him of his father's one (Horowitz, 2010: 1008). Riesman did not like the year as a helping hand on the Supreme Court nor did he accept offers he received to join one of the New Deal institutions. In 1937, he got an offer from the University of Buffalo to teach at its Law School. Looking at Riesman's list of publications, the job offer must have been based on other achievements than written ones.

Riesman had recently married Evelyn Thompson and the young couple moved to upstate New York where they remained for 4 years. For the academic year 1941–42, Riesman moved down the Hudson to spend time as a visiting fellow at Columbia University's Law School. Even before this occupationally related move, Riesman joined another broad movement, the one that brought educated and well-to-do people to the couches of psychoanalysts. In Riesman's case, it came at the 'urging' of his mother, who was a patient of Karen Horney whereas he had been commuting since 1939 to New York to see Erich Fromm (Riesman, 1988: 7). Whatever positive functions psychoanalysis might have had for the young professor, it seems that one shortcoming never burdened him: shyness

(Riesman laments his juvenile awkwardness and slow reading as hurdles, in Riesman, 1990: 24, Riesman, 1988: passim). During all the years as a young aspiring man he made the acquaintance of many people, famous and ordinary. In Manhattan, he rubbed shoulders with what became then known as the New York intellectuals and this climate was much more to his liking than the 'abstract and unempirical' world both of Friedrich's political science and the lawyers' environments at Harvard, Buffalo or Washington, DC. During his early stays in the metropolis he got in touch with Robert and Helen Lynd, Margaret Mead, and Ruth Benedict and joined the American Association for Public Opinion Research. The entry of the United States into the World War II forced the University of Buffalo, then a private institution, to close its law school and Professor Riesman had to see where he should continue his trade. He first served for 1 year as an assistant district attorney in New York and worked for the next 3 years as an executive at the Sperry Gyroscope Company on Long Island, a middle-sized war contractor firm (Anon., 2002). An article he wrote during his fellowship year at Columbia and came out in print in 1942 (Riesman, 1942) attracted the attention of Edward Shils who managed to invite Riesman for a job interview to Chicago. There Riesman started his sociological journey in 1946.

For a long period of time, Riesman was affiliated with the undergraduate College of the University of Chicago, not with any of the university's graduate departments. He started as a visiting assistant professor and became a tenured full professor the following year (Riesman, 1988: 8). The College consisted of regular faculty and Riesman belonged to the social science staff, hired primarily to teach an extensive course on social sciences for undergraduate students (Riesman, 1990). Riesman obviously enjoyed teaching and his contribution to the series devoted to autobiographies in the *Annual Review of Sociology* is dedicated mostly to his teaching experiences. A great many students came under Riesman's spell during his decades teaching social science, but his sociological writings made him even more well-known (Gans et al., 1979). One book in particular stands out from all the rest: *The Lonely Crowd*.

A Sociological Bestseller

In 1947, the interdisciplinary Committee on National Policy at Yale University, where Harold D. Lasswell pulled the strings, invited Riesman for a 1-year stay there to do some research on anything, which fell into the frame of the inviting committee. Riesman happily accepted the offer. He was able to persuade his superiors at Chicago that he would come back and found a perfect substitute to teach 'Soc2' there: C. Wright Mills. At Yale Riesman had enough funds to hire a research assistant and managed to persuade Nathan Glazer to fill this post part-time by commuting between New York and New Haven.

The book appeared in print in 1950, after less than 3 years, and has been reprinted several times, and translated into all major languages (Riesman et al., 1950, [1950]1969). The story of how *Lonely Crowd* came into being has been told by Riesman and Glazer independently and needs not to be repeated here in detail (Glazer, 2012). Instead, a kind of analytic appreciation of the book should help to grasp its nearly unique place in the postwar-social science scenery.

Looking purely at the text, one might have troubles to identify the discipline to which it belongs. The then usual form of presenting sociological research results was not observed by its author. If one would put it into the sociology basket, it would fit better with older examples, probably best be located near the two *Middletown* volumes by Robert and Helen Lynd. One is not very surprised to read in one of Riesman's memoirs that he would have been most happy, if the Lynds had invited him for another community study endeavor.

The Lonely Crowd most closely resembles books written by anthropologists in the course of World War II effort to understand the social and cultural side of the enemy nations, Japan and Germany. People with whom Riesman had made professional acquaintance the years before he started at Chicago, such as Margaret Mead and Ruth Benedict, authored books to whom Riesman paid tribute with *The Lonely Crowd's* subtitle: *A study of the changing American character*. Character was then a widely used concept, in most cases defined more closely by prefacing the term with the word 'social.' 'Social character' meant typical patterns of behavior and belief that particular societies force upon or elicit from their members. Moreover, not only outside observers but even particularly well-prepared members of a given society were thought to be able to perceive the social character of that society with some exactitude. Riesman obviously did not have any reservations with regard to any of his own prepossessions. Nowhere in the book's first edition, do readers get any hint of relativism or 'perspectivism,' as it was called by Karl Mannheim, an author Riesman obviously did not hold in high esteem, probably because of Mannheim's relativism.

The author's self-assurance is demonstrated in a then unusual usage of the first person singular. Very often Riesman speaks of himself, the author, by saying 'I,' starting as early as at the second page: "as I do throughout this book," "I do not plan to delay …," "most of these writer assume as I do – […] most of them agree – as I do," and finally "my collaborators and I base ourselves on this broad platform of agreement, and do not plan to discuss in what way these writers differ from each other and we from them" (1950: 4). Some 160 pages later, Riesman comments on the usage of 'I' by people classified as inner-directed ones. Summarizing a field exploration by some of his friends, conducted in rural Vermont, he has this to say about first person singular speech: There the old people "express feelings of responsibility for politics […] In referring to events they use the pronoun 'I': 'I' think, 'I' want, 'I' hate, and so on. They talk as if it were up to them to judge what happens in politics and, to the limits of their gifts and available energies, to guide it" (1950: 169). Very much the same could be said about the author David Riesman, who felt himself entitled to speak out about the failures of his society and politics in his country.

Besides the two classics from anthropology already mentioned, Riesman names Erich Fromm and Karen Horney, his and his mother's psychotherapists, Abram Kardiner, and Geoffrey Gorer as belonging to the orbit *Lonely Crowd* wanted to join. The social character all these authors tried to unravel was seen as one formed by parents, a relatively stable set of behaviors and beliefs within a particular society. Whereas Fromm and Horney, quite recent immigrants into the United

States, proposed to analyze modern societies as such, Riesman wanted to be one degree more down to earth and concentrated his analysis much more on his own society, that is, America. This alone put *Lonely Crowd* on a pedestal of its own and most probably contributed to its wide recognition and bestseller status (Gans, 1997).

In the 1940s and 1950s, personality and culture, personality and society, national character, and many more similar sounding publications and study programs flooded bookstores and classrooms. So, Riesman could expect that his book would be recognized in academia at least but due to his mastery of language and probably with the help of both his wife Evelyn Thompson Riesman, an experienced editor, and in particular Reuel Denney, a poet, he must have had ambitions going beyond the restricted readership of colleagues. And he succeeded. Within just a couple of month, David Riesman became a nationally recognized person. *Time Magazine* put him on its cover on 27 September 1954, announcing that 'social scientist David Riesman' will answer the question, "What is the American character?" The painting consists of a portrait of Riesman and two elderly men floating above his shoulders wearing satellite dishes as backpacks, probably an illustration of the 'other-directed character,' which occupied the center of the book.

The 300-pages-long study consists of three parts: First, Riesman outlines what he called his 'theory of character.' Second, he embeds the character types into American politics, and third, he ends with a plea for overcoming the restrictions of the character types. Crucial for the reception and the success of *Lonely Crowd* was the wording Riesman applied to the three character types outlined at length in the first part of the book: 'Tradition-directed,' 'inner-directed,' and 'other-directed.' One could be sure that the book would have got a different reception, if the author would have called his three types: T, I, and O, or 1, 2, 3. Only because of the surplus meaning in particular of 'inner' and 'other' Riesman has been able to gain the status of a diagnostician of the present.

The three types coincide with the trajectory of all societies: During the long period of static demographics – high birth and death rates balance each other – individuals are directed by tradition. Only when dynamic forces put a society on an expansive path, what later on W.W. Rostow would call the take-off, a new type of personality has to be formed: the inner-directed. Riesman locates this 'transition' to the period of Renaissance and Reformation, which means that the inner-oriented type's first appearance must have happened somewhere in Europe (more than once Riesman parallels his inner-directed type with those guided by Max Weber's Protestant Ethic). Putting all differences between Catholics and Protestants, Renaissance and Reformation, and so on, to the side, the core of the inner-directed character has to be seen in the fact that "the source of direction for the individual is 'inner' in the sense that it is implanted early in life by the elders and directed toward generalized but nonetheless inescapably destined goals" (Riesman et al., 1950: 15).

Whereas all Western civilizations were driven by inner-directed inhabitants, only 'in very recent years,' in particular parts of American society and in a handful of areas, did there emerge a new character type: "in the upper middle class of our larger cities: more prominently in New York than in Boston, in Los Angeles than in Spokane, in Cincinnati than in Chillicothe" characters were formed who, astonishingly, look 'strikingly similar' to the ones seen by the French traveler to America, Alexis Tocqueville, a century earlier. Nevertheless Riesman argues that the other-directed type 'does find itself most at home in America' and adds as the defining streaks: "What is common to all the other-directed people is that their contemporaries are the source of direction for the individual – either those known to him or those with whom he is indirectly acquainted, through friends and through the mass media" (Riesman et al., 1950: 20–21).

The contrast between a person who follows his father's instruction and the person who looks and listens primarily to his peers fills at least half of *Lonely Crowd's* pages. But only because the first was named inner-directed, and the second other-directed did readers conclude, probably correctly, that the author prefers the older over the newer type. By focusing on the then relatively new gadgets of modern life – movies, radio, yellow press media, abundance, consumerism, and personal improvement techniques – Riesman insinuated to his audience that the present might be worse than the recent past but never argued unequivocally against the present.

Lonely Crowd functioned like a Rorschach test: Every reader could come across what she wanted to read to better understand her rapidly changing environment. And indeed the US society and economy of the late 1940s was on the tip of another take-off, complete with rising earnings, increasing mobility, expanding suburbia, college education for more people, and, of course, the great baby boom. In a word, what later sociologists called Fordism, an era of full employment, mass society, mass media, and all the rest that cried out for analysis, indeed for understanding in the midst of bewildering change. Riesman, who wanted to understand himself and his contemporaries, offered Americans a portrait of themselves, very similar to the portrait *Middletown* drew two decades earlier or the portrait drawn by the huge and constant flood of diagnostics that became commonplace after *Lonely Crowd* smoothed the way.

It seems to be appropriate to file *Lonely Crowd* in the 'diagnosis of our time' genre. This type of writing assembles between two covers whatever its author has been able to collect as proof for his thesis – and this is the one big problem with this kind of reasoning. Methodologically, they are failures from the very beginning because it is always possible to find confirming instances for any thesis one wants to propose.

An Academic Life after the Bestseller

Very much different to other diagnostic writers, Riesman was open to criticism and dismissed his typology within a short period of time. In prefaces to reprints of *Lonely Crowd* and other replies to critics (see for a collection of critical comments: Lipset and Lowenthal, 1961), Riesman was willing to remove the backbone of his diagnosis. What he did not countermand was his interest in understanding the forces behind recent social changes. Since some of the criticism was directed toward the opaque methodology of *Lonely Crowd*, he and Glazer edited a second volume, *Faces in the Crowd: Individual Studies in*

Character and Politics (Riesman and Glazer, 1952) where one can find some of the empirical material corroborating the first book. Over the next decades, Riesman continued to write about his country and society, favored individualism and remained a scholar with his own style, or habitus. By bringing two concepts together one could call him a *citoyen* social researcher, which means that Riesman embodied quintessentially the concerned citizen and a scholar who preferred empiricism over abstract philosophical reasoning. What makes Riesman different to nearly all the others who want to contribute something grand intellectually seems to be his prioritizing of key questions to be raised and answered empirically, instead of clinging to abstract concepts one imposes on the world. Or, in Riesman's own words: "thinking countercyclically" (1988: 23).

Within a short period of time Riesman found another métier for his curiosity: higher education. In 1955, Paul Lazarsfeld asked Riesman whether he would be interested to do a kind of follow-up study of a quite recently finished survey, which became *The Academic Mind* (Lazarsfeld and Thielens, [1958] 1977). In this study, Lazarsfeld examined the side effects of the hysterical mood caused by the anti-Communist crusade, usually called by the name of its fiercest spokesman, Senator Joseph McCarthy. The former law professor and now best-known public intellectual David Riesman, with several publications on civil liberties on his *curriculum vitae* seemed to be the best choice to contribute a separate investigation of the validity of the questionnaire as an instrument. Riesman accepted and made himself familiar with the diversity of higher education institutions in the United States by visiting more than four dozen of them personally (Riesman, 1979).

When his close friend Everett C. Hughes lost the battle over the University of Chicago's sociology department's chairmanship, Riesman accepted an invitation by his old university and returned to Harvard, where he continued to give undergraduate courses under the title 'American character and social structure.' During the next couple of years Riesman published several books on higher education, mostly coauthored with junior faculty (best known is probably Jencks and Riesman *The Academic Revolution* from 1969), and continued to write magazine articles and commentaries for a larger audience (see Riesman, 1954, 1964). The student movement of the 1960s did not meet with his approval and he did not refrain from confronting the rebels with his arguments. Since Riesman did not scorn popular culture – in *Lonely Crowd* he even quotes children rhymes – he might have gotten some satisfaction when Bob Dylan paid tribute to the title of his bestseller: "Standing next to me in this lonely crowd/Is a man who swears he's not to blame."

In the social sciences Riesman's name can still be remembered by insiders but from his huge *oeuvre* only one title survived. Orlando Patterson was not right to call him the last sociologist (Patterson, 2002), but he was right insofar as scholars like Riesman are now available only in the history books of the social and behavioral sciences – most probably not to their advantage.

Right to the City: A Liberal-Democratic Perspective

Abstract

Over the last four decades, the concept 'the right to the city,' first developed by French philosopher Henry Lefebvre, has traveled from Europe to the rest of the world. This article discusses the key questions relating to the right to the city, and provides an overview of the evolution of this concept and how this abstract concept has inspired and empowered the struggles to fight against capitalist globalization worldwide, in particular the global south. In the global north, the right to the city has been widely exploited as an important tool to safeguard citizen's equal access to scarce social resources and opportunities, whereas in the global south, its enlightening power is being actively excavated to foster social equity, civil society, and democracy. The creative exploitation of this concept has been put in place in a variety of locales and leads to the enactment of a number of extended agenda locally and internationally. The enduring global economic recession provides opportunities for more expansive and interconnected exercises of the right to the city through allying the North and the South.

Originally formulated by French philosopher Henri Lefebvre, the idea of 'right to the city' was first inscribed as the right to 'renewed centrality, to places of encounter and exchange, to life rhythms and time uses' (Lefebvre, 1996[1968]: p. 179). Essentially, this thesis advocates for a vision of a life fully lived for urban inhabitants. The crux of the thesis emphasizes use values as the organizing principles of urban spaces, though the use values have been radically encroached by exchange values and colonized by the dominant classes in a world prevailed by capitalist globalization. Written just before the 1968 student riots in Paris, the right to the city thesis was rising from crisis and continues to face different crises today, from the crises of Fordism to the crises of Neoliberalism. The currently enduring global economic recession further exposes the inherent crisis and conflicts invariably piled up under the imperatives of neoliberalism over the last three decades, and leads to the outbreaks of political and legitimation crisis simultaneously. Nonetheless, these crises have offered challenges and opportunities for the dissemination and implementation of the right to the city worldwide.

Since the date of formulation, the right to the city has been widely (re)interpreted and excavated in academia, and extensively implemented in urban social movements and policy making. Building upon Lefebvre's original writings, Harvey (1973) made a focused and thoughtful attempt at interpreting the right to the city and social justice, by defining the right to the city as a collective right to the democratic management of urban resources based on a threefold criteria – need, contribution to common goods, and merit. The idea of the right to the city soon traveled from Anglo-North America to the rest of the world with its resonance found among activists and policy makers. Castells (1977) further developed this theory through offering a normative definition for urban social movements, which are considered to be the highest level of citizen action that brings about radical changes in political power or specific outcomes in the political arena, or redefines the urban system and its meanings. More recently, the idea of the right to the city has been commonly incorporated into the discussions on gentrification, immigration, housing, citizenship, urban public space, and social exclusion (see Amin and Thrift, 2002; Dikeç, 2001; Harvey, 2008; Mitchell, 2003). This can be seen as a restoration of critical urban theory and an endeavor to seek for a more democratic urban politics.

Apart from being a 'political ideal,' the right to the city has literately become 'a working slogan' inspiring and empowering numerous urban social movements worldwide. The idea is also articulated in a number of charters promoting justice, sustainability, and inclusion in cities, such as the World Charter for the Right to the City, the European Charter for Human Rights in the City, the Montreal Charter of Rights and Responsibilities, and the Mexico City Charter for the Right to the City, just to name a few. In translating the theory into practice, controversies and incongruences occurred among academics, activists, and international initiatives. Yet, efforts have been made to bridge the theoretical and practical explorations of the powerful idea of the right to the city.

Evolution of the Concept

Lefebvre's original writings on the right to the city challenge the social and political urban structures of the twentieth century, by proposing a new type of 'citizenship' at the urban level, distinct from the formal citizenship of the nation-state, to embrace heterogeneity, shared space, and societal ethics. This citizenship is to be achieved through public participation and democratic practices (Harvey, 2008). In the past four decades, the concept of the right to the city has evolved through the works of social activists and academics, the growing social and environmental awareness in the 1960s–90s, and recent innovations in social practice. It has been elaborated and practiced at different scales, from individual, household, and neighborhood level to the city level and beyond. The right to the city now encapsulates expansive conceptual and practical meanings, including the right to political space, the right to public space and housing space, the right to autonomy, and the right against state domination and policy brutality. It might be

associated with a variety of meanings and elaborations, fundamentally it is an outcry for social justice, a potent quest for the rights of various social groups in the city, and a compelling antithesis of the widely implemented neoliberal agenda. Most importantly, apart from informing and inspiring the daily struggles for specific city rights, it can also be turned into a more powerful and inclusive concept to encompass people's 'freedom to make and remake our cities and ourselves' (Harvey, 2008: p. 23). Apparently, the right to the city needs to be understood as a multiscalar and multilayer concept bearing millions of possibilities for seeking and creating a brighter urban future.

As one of the most influential urban theories, the right to the city has invoked heated debates and constant contemplations, and thus gives rise to the important questions of 'whose right is it about, what right is it and to what city?' (Marcuse, 2009: p. 185). Answering these questions would be crucial to fully comprehend the rich conation of the concept both as a critical urban theory and a working slogan in social practices. These questions also carve the story line of the evolving concept, and shape future opportunities for the development and application of the idea.

Whose Rights

Among academics and activisms, a strong belief is held that the right to the city entails the possibilities for enfranchisement and social inclusion, which eventually benefit all urban inhabitants. In this sense, a broader concept of citizenship is embedded in the right to the city thesis. It has been widely recognized that one's everyday experience of inhabiting the city rather than one's nation-state citizenship constitutes the substantive and meaningful citizenship. In practice, numerous attempts have been made to bring about a more inclusive citizenship. For instance, the Montreal charter has made possible a joint declaration by the state and citizens to ensure that citizens enjoy all sorts of rights to the city, and redefine "citizens" as "any person living within the city territory" (Brown and Kristiansen, 2008). Meanwhile, some scholars have made clear distinction between this new type of citizenship based on inhabitance and the conventional notion of national citizenship (Brown and Kristiansen, 2008). Specifically, some scholars propose disposable urban citizenships or multiple citizenships based on residency and place of work, which could be taken up on arrival but abandoned on departure (Bauböck, 2003). These endeavors have widened the definitions of citizenship and who has a right to the city based on residency. However, they still exclude the majority of the urban poor, such as migrants, workers in the informal economy, refugees and immigrants without legal documents, and commuters who go back and forth between different places on a daily basis. Apparently, framing citizenship in formal and territorial terms has failed to take urban politics and the social relations of power into account (Dikeç and Gilbert, 2002).

Therefore, the 'rights to the city' need to be defined with cautions to safeguard the livelihood and interests for the urban marginalized people. It should be the right for inhabitants of cities, especially those without citizenship or 'proper' documentations. Without bearing this in mind, the so-called 'slum-free' movements in support of the free-market ethos would be turned into a nightmare for a vast volume of dwellers in the substandard settlements in the developing world. Attending to these potential problems, Mark Purcell (2005: p. 14) contended that the right to the city must be ascribed to those who 'live in the city, who contribute to the body of lived experience and lived space.'

In addition, the rights to the city also include the right to difference, i.e., different race, ethnicity, class, and culture. This is of great significance in an age of globalization when flows of population have reached unprecedented speed and scale. More specifically, Peter Marcuse (2009) assigns the right to the city to those treated unjustly, those in want, oppressed, and dispossessed: the homeless, the disabled, the hungry, impoverished, and unemployed, and those disrespected and treated unequally: immigrants, racial minorities, sexual minorities, political activists, and so forth. For these people, the right to the city can be turned into a powerful weapon to fight against any forms of unjust hegemonic power and policies.

What Rights

Although there is little controversies on whose right the right to the city thesis entails, it has not been clearly stated in Lefebvre's original writings what kind of rights they should be. It has been widely recognized that the right to the city should be promoted as a collective right rather than specific and individual rights (Harvey, 2008). It might be more accurate to put it this way: the collective right to the city advocated by Harvey and others may include, but is not confined by specific rights – such as the right to housing, right to public space, or right to employment. In social practices, the right to the city has been rendered certain flexibility and openness. In many instances, it is a socioeconomic right, e.g., a right to housing, to transportation, and to natural resources like water. In other instances, the right to the city is more of a right to a communal good, like community, tradition, and culture. Such openness and fuzziness is not necessarily bad. Mitchell and Heynen (2009: p. 616) rightly point out the value of the concept of the right to the city 'is precisely its capaciousness,' 'because it allows for solidarity across political struggles, while at the same time focusing attention on the most basic condition of survivability.'

In general, the right to the city incorporates two principal rights: the right to participation and the right of appropriation. The right of appropriation refers to the rights of city residents to access and to make use of city space. The right to participation means that urban residents should have the opportunity and power to redefine and transform the urban space. In a similar vein, Harvey (2003: p. 939) proposes two sets of rights "the right to the city is not merely a right of access to what already exists, but a right to change it after our heart's desire," i.e., the right of now and the right of future. In addition, Douglass and Friedmann (1998) identify three claims for rights – the rights to voice, to difference, and to human flourishing. These claims, in particular the last point, have resonance with the vision of 'a life fully lived' advocated by Lefebvre. In sum, the right to the city is a set of tool kits for radical urban change, which generates opportunities and space for citizens to address and access their needs. To reach that end and to achieve substantive

citizenship, citizens must claim rights of participation, in addition to gaining access to rights of appropriation.

Overall, the right to the city encompasses rights of many kinds, be it a socioeconomic right or a liberty right, a legal right or a moral right, a prima facie right or an absolute right (Attoh, 2011). Hence, the right to the city constitutes not a singular right, but a bundle of connected rights. That said, these different rights claims might be in conflict with one another. As any other types of rights, the right to the city is not free of conflict and trade-off. For instance, David Harvey (2008) sees the right to the city as a collective right to the democratic management of urban resources, yet Don Mitchell (2003) illustrates the conflicts between the right to the city of the homeless and the 'democratic' management of public space. The question of what kind of right is a right to the city could serve to reveal the level of incoherence within the current debate and therefore to sharpen the right to the city's political edge. And one possible way to square such conflicts is to integrate the right to the city into a general theory of social justice or substantive democracy (Attoh, 2011).

To What City?

Despite some inherent incongruence, there are some common values shared by different adaptation of 'right to the city' envisioned by the academic, policy, and activist circles. Essentially, the right to the city looks beyond the physical space of the city, by interrogating all power structures and social relations determining the lives and experiences of urban inhabitants. In this sense, arduous tasks remain to be done to reach the city embraced by all its inhabitants, through combating against various influences and structures dictated by capitalist values.

To best address the political ideal remaining unreachable and to contrast the reality and ideal, Lefebvre had deliberately distinguished the 'city' from the 'urban.' The 'city' might be torn by corporate culture and dominant neoliberal agenda, while 'the urban' is a society beyond capitalism, a connected space shared by inhabitants and supported by meaningful social interactions (Purcell, 2013). The right to the city is therefore a struggle to take back urban space from capitalism and return it to its inhabitants. The struggles for the right to the city are therefore essentially the battles for the inhabitants who make the city a meaningful space to repossess the use value of urban space from the property rights owners chasing for exchange values. Claiming the right to the city is to restore the contaminated and comprised city to rediscover the urban and make it flourish (Purcell, 2013). For Lefebvre, 'the urban' foretells a revolution consisted of millions of everyday struggles and innovations, and can only be achieved through sustained political struggles.

As an important concept integrated to the right to the city thesis, *autogestion* – 'self-management' or 'worker control' – suggests replacing the powerful state-centered organizations with democratic management by citizen themselves through radical, democratic political mobilization and decentralization of political power (Lefebvre, 2001). Based on this idea, the vision of an ideal city would be "a city of centrality, access to information, truly broad participation and enfranchisement, of unalienated labor, and offering the opportunity to live life to the fullest" (McCann, 2002: p. 78).

Bridging 'Political Ideal' and 'Working Slogan'

Under the overarching framework of the right to the city, activists and international initiatives have led the challenge of translating the right to the city into practice worldwide, through urban social movements and institutionalization/legalization of the right to the city. In the global north, urban social movements have evolved to fight against dominant development paradigms over the past four decades, from urban renewal of the 1970s, to the sweeping neoliberalization of the 1980s, to the frenzy for local economic development of the 1990s, to the post-2000 highly unjust financial and property markets (Mayer, 2009). In the South, urban social movements have long been interwoven with the fight for basic human rights and political freedoms, e.g., claims for access to clean water, shelter, and dependable livelihoods. Meanwhile, other movements are also actively fighting against globalization and global justice to challenge the dominant economic system, and to contest the urban system shaped by the logic of capital. For instance, the Right to the City Alliance, a network of community organizations in the United States, was launched in 2007, bringing together community-based organizations to deal with various urban problems, such as gentrification, environmental justice, homelessness, cultural preservation, juvenile justice, and the well-being of gay, lesbian, bisexual, and transgender youth (Purcell, 2013). A similar effort began in Europe in 2010 to organize the networks of activist groups under the right to the city as an umbrella idea.

In the past four decades, the right to the city has not only informed activists in various social movements, but has also been incorporated into formal legislation and institutions, and officially employed as a vehicle for social inclusion and well-being for various excluded and alienated urban groups by a number of municipal, regional, national, and international organizations. Examples include Habitat International Coalition, the Centre on Housing Rights and Evictions, Action Aid, and the National Forum for Urban Reform, the World Charter, the Montréal Charter of Rights and Responsibilities, the Aberdeen Agenda of the Commonwealth Local Government Forum, the Brazil City Statute of 2001, and the Urban Policies and the Right to the City research project launched by UNESCO with UN-HABITAT (Brown and Kristiansen, 2008). Among them, World Charter is probably the most influential one, with its principles being adopted widely while not becoming an official legal document itself.

However, translating the critical theory of the right to the city into practice is not free of controversies. Some contemporary initiatives launched by international institutions are accused of limiting their claims to granting or institutionalizing the rights for certain disadvantaged groups through state legislation, while others are blamed for remaining as a tamed negotiation with the capital machinery ruling the world. These initiatives are considered drifting too far away from Lefebvre's original exhortation for going beyond the state and capitalism through radical struggles (Mayer, 2009). For these reasons, the

extensive use of the right to the city by certain global NGOs is considered losing its political edge (Mayer, 2009; Purcell, 2013). Their goals are often stated as 'inclusion' aiming to integrate currently excluded groups into the structures of government and the formal economy. Purcell (2013) further points out another drawback of contemporary initiatives which tend to confine the right to the city within a liberal-democratic framework, by granting people a relatively weak measure of democratic control through a set of state apparatus such as elections, parties, laws, and stable state institutions. Under this framework, the right to the city is at best proposed as a modest addition to the list of existing liberal-democratic rights, without challenging its legal foundation and inherent problems. For this sake, Purcell (2013) advocates returning to the pristine meaning of the right to the city to radicalize and inform political actions. By so doing, it is believed that a radical democratic society beyond state and capitalism can be formed by urban inhabitants themselves collectively. In this sense, the right to the city should be treated as political claims made by the mobilized groups. For Lefebvre, even though the horizon of '*autogestion*' will never be reached, it is of great importance to arouse the awareness and determination of struggles toward the horizon through the contractual citizenship binding the citizen together based on collective action and self-management.

On the other hand, for movements fighting against the capitalist urban system which are often equipped with a bottom-up approach and radical quests, such as the Right to the City Alliance in the USA and similar urban movements across Europe, they are deemed to be a direct response to Lefebvre's exhortation to create and claim rights to the city through social and political actions. In this sense, the right to the city is less a legal right, but rather a radical claim to subvert the extant social structure and system ruled by the rich and powerful. This revolutionary form of appropriation to the city space is considered to have a closer link to the Lefebvre's original idea.

Given the fact that the right to the city is so widely practiced in social movements and international initiatives, how the claim is perceived and interpreted would be rather different. While radical scholars tend to interpret the ultimate goal of the right to the city as to eventually disintegrate the relationship between citizens and the state (Purcell, 2013), others are accentuating the important role of government, particularly local government, in implementing the right to the city, as an intermediary between the urban poor and the global economy (Brown, 2013), or employing the concept to ameliorate the intensified confrontation between the 'have' and the 'have not,' by emphasizing the right to the city as a collective right. In many cases, the right to the city is also exploited to better achieve social and economic justice for poor people in urban areas, by prioritizing the social function of property and the city, and incorporating these principles within constitutional and statutory provisions and employing these principles at the local level through ambitious and innovative property programs (Pindell, 2006). Contrasting views on these social practices are also found among academics. On the one hand, Margit Mayer (2009) tends to contrasts those who seek to create rights through social and political actions with those international NGOs and UN programs seeking institutionalization of rights through legislation and city charters, to advocate for radical politics. On the other, Brown (2013) points out the limitation of 'radical politics' advocated by Mayer (2009) and others to confront the immediate problems suffered by citizens in the global south, and the danger to wipe out the potential for fundamental, legal, and institutional reform to make a fairer contract between state and citizen in the long run. She further contends that radical revolution and confrontation should be taken as a last resort to challenge oppression of rights to the city. In particular in the context of global south, radical confrontation and violent struggles could cause enormous aftermath for individuals and the country as a whole that might take decades to recover. Alternatively, Brown (2013) is in support of Fernandes' (2007) accentuation on the important role of legal and political order to change the exclusionary nature of urban development and to do justice to informal development in developing countries. Yet, this is not to suggest that the right to the city is reduced to the right to be remained in the city, or to be housed and serviced. The right to the city in fact holds real potential for liberal democracy, for enfranchisement, and social inclusion (Purcell, 2013).

To bridge the two ends of the right to the city both as 'political ideal' and 'working slogan,' Harvey (2001) gave a more pragmatic formula to exercise the right to the city, by contending that insurgent politics and grassroots activism may provide a route for realizing social change, as "transformative politics are constantly intermingling with local mobilizations," but needs to go beyond local concerns. In a similar vein, Brown (2013) points out that the most powerful agendas and exciting ideas will emerge from the intersection between creative theory and grounded practice of those addressing critical problems faced by the deprived and the alienated, especially those in the global south.

In addition, a fuller understanding of the right to the city and its practices also calls for a multiscalar reading. It is quite clear that the right to the city is to be understood and implemented at the city scale. Yet the exercise of the right to the city can be played out and be reached out by stakeholders at different scales: regional, national, international, and intraurban. Adding to the alteration in national legislation, changes in local institutions, including city governments and grassroots organizations, are also crucial to translate the right to the city into practice. At the intraurban scale, public space has long been the focal point of rights struggles in both the North and South. It has become the arena of claiming for democratic rights, and the shelter for those excluded from the commodified private domain, but is increasingly policed and controlled (Brown, 2013). Meanwhile, public space functions as a key forum for debates on rights and citizenship, particularly in societies dominated by corporate culture and 'big capital,' where the idea of citizen's rights to public urban space are rapidly obscured as corporate space has quietly penetrated into social space (Cuthbert and McKinnell, 1997). Having said that the exercises of the right to the city need to be examined at various scales, it also relies on a careful examination on the relationship between state and citizen, so as to reframe the configuration of 'the bundle of rights,' and redefine the connotation of

citizenship, through constant social struggles and intellectual contemplations.

The Right to the City in Global South and Beyond

Cities of the global south have been moving steadily from the margin to the center, demographically, economically, socially, and politically. The surging research interests in 'Southern urbanism' are certainly a significant progress going beyond understanding cities in the South based on 'Northern/Western theories.' If the 'right to the city' in the global north is often associated with democracy and social equality, in the global south, the concept deals more specifically with citizenship, housing rights, the right against forced eviction and the right of squatting (Davis, 2006; Fernandes and Varley, 1998), and the rights to livelihood that are often claimed through informal economic activities in public space. In the emerging economies and newly industrialized zones, the right to the city is of particular significance for the large volume of rural-turned urban population, who are often turned into the urban underclass. Similarly, in the context of transitional economies, a systemic transition from planned economy to market system ignites waves of rights-claiming movements, in which the rights to the city can be seen as a broad set of collective and individual rights concerning both the poor and the middle class against the party state and its neoliberal policies (Gainsborough, 2002; He, 2007; Sykora, 2005). City spaces have increasingly become a highly contested ground where diverse interest groups seek rights to survive, inhabit, and thrive. Some of these claims are modest, e.g., acquiring a livelihood and a living space of one's own, whereas others are more ambitious in its scope, e.g., challenging the predatory capitalist system through revolutionary movements. Regardless of the patterns and strengths of the struggles for the right to the city, the efforts of the fighters, in particular the less privileged urban social groups, will not only bring about a better life for themselves, but also have the potential to reshape the urbanization trajectories of their cities where elite groups have steered the courses of urban change under the imperatives of neoliberal accumulation regime (He and Chen, 2012).

Representing two rising powers in the world economy and political stage, Brazil and China exemplify two different stages and strategies of right to the city. In Brazil, the installation of City Statue gave priority to the social function of the city so as to safeguard city residents' rights of participation and occupation. In general, it has broadened the opportunities for urban inhabitants to actively participate in land use planning processes and has opened up the opportunities for them to acquire legally recognized property rights. The most remarkable change in Brazilian legislative system is granting legal property rights to the 'squatters.' Its major achievement should not be understood simply as sheltering the squatters alone, but should be interpreted as a bold attempt to entitle the poor and the marginalized with the opportunities to effectively access housing and shelter. It also sows the seeds for hope to fully access to a bundle of rights to the city beyond the right to housing, eventually to reshape the city in a way through which all inhabitants could have a fully lived life. Besides the installation of City Statue in Brazil, the right to the city has also been adopted elsewhere in Latin America, e.g., in Colombia's law no. 388/1997, Article 31 of Ecuador's 2008 Constitution, in housing rights in Chile, and in the Charter for the Right to the City in Mexico City (Brown, 2013). Certainly, these initiatives will not solve all the problems commonly faced by these countries, nonetheless the way how they are executed and stretch out to other spheres and other contexts will be critical to progress the fundamental reform that the right to the city entails. At the local level, empowered by the right to the city, struggles either in the form of resistance or participation are prevalent across Latin America, e.g., appropriating public space through Mexican 'public cultural spectacle' and 'symbolic spatial practices' (Villa, 2000), protests, and demonstrations following the tradition of 'taking to the streets' (Friedmann, 1992). This tradition not only transforms the urban social landscapes in Latin America, but is also taken up as a weapon fighting against various crises persisted in the neoliberal urban system in other locales.

In China, it was quite unusual to see urbanites seeking for any kind of right to the city under socialism. With different forms of dispossession revolving around rights to urban spaces becoming ubiquitous, Chinese cities have seen a rise of the '*weiquan*' (meaning defending rights) movements. Yet, so far urban social movements in China are still limited to a very small proportion of the urban population, mainly seen in two forms: labor protests led by laid-off workers and migrant workers, and property rights defending by homeowners (see Cai, 2002; Friedman, 2009; Lee, 2007). As the country and its dominating class have voluntarily subscribed to the neoliberal urban ideology with intense commodification of urban spaces, several tiers of citizenship are taking shape in the Chinese city, especially after marketization and neoliberalization taking up speed since the 1990s. Class stratification is formed among rural migrants and formal urban citizens of different statues. Among the latter, former socialist workers who became the new urban proletarian and the emerging *nouveau riche* who gains a windfall fortune during the economic reform are two contrasting social groups. For both rural migrants and other urban underclass alike, their rights to the use values of city spaces are vulnerable to be traded off by the exchange values of city spaces, which are often dominated by the emerging affluent class in order to maintain or redefine their class status in a rapidly changing society. Subjected to the dual forces of institutional inheritance from the socialist period and the capitalist imperatives introduced by the market reforms, the development path of the present-day Chinese city is featuring suppressed rights to the city, especially for those deprived by both forces. In this sense, the right to the city could potentially serve as a powerful weapon to fight against the emerging urbanism dominated by intensified inequality and marginality. Although over a long period of time, most Chinese urbanites chose to remain as the 'silent majority' in face of social inequalities, the installation of the Law of Property Rights in 2007 and the constantly enlarging volume of work done by NGOs and activists have profoundly wakened their consciousness of the right to the city. However, confined by the existing legislative framework and rigid political control, most urban social movements in China remain as individual

struggles, most commonly exemplified in the 'nail household' phenomenon which largely aims to bargain for better compensation packages, or limit to claiming economic rights rather than political rights and citizenship. Whereas the magnitude and amplitude of urban social movements under the rubric of the right to the city in China are not comparable to those in Latin America, the rising consciousness of rights to the city and diverse struggle tactics fighting against social inequality are encouragingly progressing. For instance, amidst the surging waves of gentrification in Guangzhou, the third largest city in China, local residents have started to progress from claiming the rights to appropriation of housing space to claiming the rights to participation in urban redevelopment decision making (He, 2012). In the meantime, under the conceptual framework of the right to the city, scholarly work has been done to interrogate how the remaking of the Chinese city is being shaped by the imperative of capital accumulation and by the subordination of social interests and marginal groups to the neoliberal forces emanating from different spatial scales, also to understand those bottom-up struggles to contest the unequal rights (see He and Chen, 2012; Qian and He, 2012).

In the global south, social inequality and poverty are pandemic, be it in Latin America or China. Several themes are at the frontier of struggles for the right to the city, such as contested public space, informal settlement/slum redevelopment, fast building of new towns/cities or the so-called 'instant urbanism,' various forms of enclaves associated with 'splintering urbanism,' and rigid urban governance as neoliberal institutional apparatus (Samara et al., 2013). Of course, these themes are not unique to the global south, which are recurring in different locales and becoming the focal point of rights struggles. It is worth noting that the breath and intensity of right struggles in global south are definitely unprecedented in the north, and are thus of great potential to cultivate revolutionary transformations to achieve the ultimate goal of the right to the city. Nowadays, in North American suburbs where the aftermath of the subprime crisis is still pandemic, people are picking up the strategies of land rights claiming from the global south, where a tradition of taking rights struggles to the street and legislative endeavors has long existed.

Along with the sizable and influential urban social movements, the achievements of international initiatives such as UN, and legislative endeavors at national level, e.g., the City Statue in Brazil, academic work on the global south has now acquired a distinct body of scholarship with its own questions, approaches, and contributions to the right to the city literature (Samara et al., 2013). This scholarship has started to bridge with and inform the social practices and academics in the north, as the two poles of the urban world increasingly bend toward each other in some important ways (Smith, 2002), accompanying the constantly unfolding global economic recession starting from 2007. As a harbinger bridging the South and North scholarship, Castells (1977) offers a comparative perspective between the cities of South America and of Europe, which are sensitive to cultural and political particularities of the South. In addition, Mayer (2009) explicitly foretells the possible opportunities for the right to the city in an age of globalization: a variety of social urban movements has become intricately linked alongside the world economy. In certain ways, the global economic recession justifies urban social movements' claims and arguments about the unsustainability and destructiveness of the neoliberal growth model. Such a situation also defends the ultimate declaration of the right to the city and expands the opportunities to make it work, and advocates for democratizing cities and their decision-making processes. Through exposing and politicizing the implications of the current global crisis, in particular the outrageous environmental, social, and political problems, social movements for the right to the city could make good use of these opportunities (Mayer, 2009). Evidently, the global south is becoming the epicenter both for social struggles for the right to the city and cutting-edge urban theories development deriving from the so-called 'Southern Urbanism.'

Rights: Legal Aspects

Michael McCann and Stuart Scheingold[†], University of Washington, Seattle, WA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The language of legal rights generally connotes potentially enforceable claims of entitlement to certain freedoms, goods, or conditions. Rights traditionally have been identified with Western liberal constitutional regimes, but non-Western foundations and international human rights conventions have become increasingly salient in contemporary world politics. This article reviews a wide range of perspectives about how rights are conceptualized and critically assessed by legal philosophers, jurisprudential analysts, and empirical social scientists.

Definition and Background

The Basic Logic of Rights

The language of rights generally connotes potentially enforceable claims of entitlement to certain freedoms, goods, or conditions. To assert that 'I have a right …' is to articulate a normative claim that certain actions should or should not be performed by other individuals, agencies of the state, or intermediate social institutions. As such, rights are related to, but different from, preferences, interests, and needs. Although rights are often invoked in the service of preferences and interests, only those rights that confer legal and/or moral authority that obligate others are enforceable by official authority. Whereas the assertion of a preference connotes merely that 'I want…,' to assert a right is to declare that 'I am entitled to….' Rights thus assume priority in the normative schemes of social ordering; they take priority over – or 'trump', as Ronald Dworkin (1984) memorably said – preferences and interests. Rights similarly take precedence over needs in much the same way, but with one major difference: needs, unlike preferences, convey an objective status that can be validated by parties other than the claimants themselves. This feature is underlined by the fact that rights are invested with general authority by the constitutional and statutory texts in which they are enumerated, by judicial constructions within various governmental orders, and by the potential for state enforcement. Although claims to rights are subject to third-party validation and enforcement, they are typically initiated by individual agents or groups acting on their own behalf (Waldron, 1996).

Because rights constitute relationships between the bearers of rights and other persons or institutions, each person's legal rights impose correlative duties on others. These duties may be *negative* in that they mandate noninterference or inaction by others, as in one's claim of a right to liberty, privacy, or autonomy. Conversely, the duties imposed by rights may be *positive* in that other parties are called upon for action and assistance – as, for example, to ensure the fulfillment of contractual terms or to provide accessible facilities for voting in political elections. Rights may be primarily negative or primarily positive, but they may also involve elements of both.

Similarly, the exercise of rights typically confers responsibilities on the rights-bearer. For example, a person may have a basic right to own property, but the right imposes enforceable responsibilities that limit activity of the property owner that causes harms to other property owners or citizens. Finally, violations of rights typically authorize legal remedies to rights claimants. Thus, for example, not only does the right to equal treatment oblige others to refrain from invidious racial discrimination, but should wrongful discrimination occur, the right to equal treatment requires a legal remedy to compensate for and/or to correct the denial of a basic entitlement.

The Origin and Evolution of Rights

The most widely recognized origin of liberal rights is in European social contract theory dating back to the seventeenth century, and especially to John Locke's classic *Two Treatises on Government*. From this work, rights emerged as a moral imperative that is found at the very core of several of the most important political documents in the modern age, including the United States Declaration of Independence as well as the Bill of Rights, and the French Declaration of the Rights of Man and Citizen. Although the concept of rights thus dates back several hundred years, and has provided a founding principle for several long-standing liberal constitutional orders, it is in the second half of the twentieth century that the moral ethos of rights took on widespread significance around the world. The persuasive power of rights developed in part in reaction to horrors of authoritarian states – Hitler's genocide, Stalin's purges, colonial repression, and the like – and in part in recognition of deprivations suffered by ethnic and racial minorities, women, sexual minorities, and other marginalized groups in nations throughout the world.

The Expanding Variety of Rights Claims

The evolution and diffusion of rights through the centuries and around the globe has been boiled down by analysts to three separate forms, or generations, of rights claims.

First-Generation Rights

These are closely linked to the rule of law and to liberal social contract theory; they are regularly found in the constitutions of liberal democratic regimes throughout the world, as well as in

[†] Deceased.

such transnational legal orders as the European Convention on Human Rights. First-generation, or classic, rights are embedded in the logic of both property ownership and the rule of law itself. On one hand, such rights tend toward the more negative pole, demarcate limits on interference by the state or other social actors, and turn on conceptions of liberty, privacy, due process, and the like. On the other hand, classic first-generation rights also include more positive rights to political participation – to free speech and association, to vote, to run for office, and so forth – and to fair treatment by others according to the principles of due process and equal protection. These rights claims are the most widely recognized and the least contested in general, although specific constructions vary greatly across time and jurisdictional space.

Second-Generation Rights

These can be traced to the social democratic traditions of Europe and Latin America but have during the last century gained currency elsewhere – although not so much in the United States. Second-generation rights have to do primarily with entitlements to economic and social well-being of the sort formulated in Articles 22–27 of the Universal Declaration of Human Rights (1948) – including, for example, basic education, health care, minimum income, secure employment, workplace organization, food, housing, social security, and the like. While first-generation rights have been celebrated as resources for challenging excessive state violence and making governments more accountable, many analysts find that second-generation socioeconomic rights, which usually require wealth redistribution, have generally proved less potent sociolegal conventions.

Third-Generation Rights

These are newer in conception, different in kind, and particularly controversial. Advocates of third-generation rights seek to confer entitlements to nonindividualistic, or communal, goods such as peace, security, a healthy environment, natural resource preservation, group self-determination or sovereignty, and animal welfare. The challenge posed by third-generation rights, which compounds the limited realization in practice of second-generation rights, will be addressed below.

Rights beyond the Liberal Western Tradition

A widely varied and robust area of academic inquiry in recent decades, largely responding to the palpable expansion of rights talk around the world, has addressed the development of rights-like conventions in many different religious and ethnic traditions. Scholars differ about whether, or how much, these traditions developed independent of Western influence or from historical encounter with Western cultural power and especially colonial influence. For example, Feldman (2000) argues that, contrary to long-held views about the strong cultural traditions that emphasize social harmony, Japanese citizens have long enacted general conceptions of rights and engaged in both individual and collective rights-based disputing. Many scholars likewise have identified the strong traditions of rights – including social and economic rights as well as private and political rights – that developed historically in Latin America prior to the twentieth century and contributed in unique ways to the development of human rights (see Wright-Carozza, 2003). Other scholars have demonstrated how rights traditions have developed in Muslim societies, sometimes independently and sometimes as hybrid constructions of sharia practices and Western secular rights traditions (Osanloo, 2009). Indeed, many scholars predict that such hybrid constructions will continue to proliferate around the world as international conventions on human rights are 'translated' and adapted to fit the wide variety of local traditions (Merry, 2006).

Contemporary Philosophical Debates about Liberal Legal Rights

The original conceptions of so-called liberal Western thinkers in the social contract tradition grounded rights in the theocratic logic of God's divine plan and natural law. Later versions downplayed the divine hand but continued the emphasis on rights as self-evident and inalienable features sewn into the rational order of the natural universe or human nature. By the twentieth century, the philosophical foundations for rights became thoroughly secular – whether justified by various forms of moral rationality or appeals to proven historical efficacy. The tensions among these diverse legitimating logics have defined the terrain for many of the most important philosophical controversies about rights. We identify just a few of such persistent debates, which mostly refer to Western liberal traditions in the United States and Europe.

'Nonsense Built on Stilts'

This critique, which can be traced back at least to Jeremy Bentham and continues today among critical 'neorealist' philosophers, turns on the recognition that rights are indeterminate (see Tushnet, 1984). Its core contention is that if rights are indeterminate and contingent, if they always are changing, and vary with context, then they really mean little at all and convey no real social power. Rights, it is argued, are simply moral or legal fictions that possess none of the objectivity, coherence, independence, and universality that philosophers, state officials, and popular culture assign to them. At best, rights are epiphenomenal reflections and rationalizations for relations grounded in other types of causal forces or power structures. Respondents to this position acknowledge that rights are social constructions, but the very fact that people believe that rights matter and act accordingly in interpersonal relations, often in the shadow of official enforcement, demonstrates the power of rights. It is further argued that all moral discourses are indeterminate and that it is, therefore, inappropriate to dismiss rights discourses as meaningless because they are unstable and contestable. Indeed, according to this argument, the indeterminacy of rights discourse, as with moral and legal discourse more generally, is desirable in providing a flexible, dynamic, and pragmatic tradition for ordering social relations in authoritative, just ways.

Who Has Rights?

The debate over the qualifications for rights-bearing is as old as the concept itself and has expanded among moral philosophers

and jurisprudes as specific rights claims themselves have proliferated. From the start, rights typically have been understood to be properties belonging to all individual human agents. Legal rights are thus often understood as inclusive and universalistic, belonging to all capable humans. Because rights traditionally have been authorized and enforced by nation states, though, legal rights have often been the prerogative of recognized citizens in specific sovereign domains. Indeed, it is commonplace to recognize that national citizenship confers the legal 'right to have rights.'

Somewhat ironically, though, this designation of rights-bearers as qualified human agents has limited the reach of, and some might say betrayed, the promise of rights, including both general citizenship rights and specific rights entitlements. Indeed, the claim that rights apply only to rational, disciplined, educated, human agents capable of self-government has been invoked to deny legal rights to children, women, ethnic and racial minorities, religious adherents, immigrants, and others in many societies that generally recognize individual rights (see Williams, 1991). Similarly, the principle that rights inherently presume qualified individual human claimants has been central to contemporary arguments that third-generation entitlements of animals and other nonhuman forms of life (e.g., trees), as well as nondivisible communal goods such as peace and a safe environment, are not suitable for rights claims. The philosophical skeptics argue that such claims lack theoretical coherence and might even undermine the social power of rights discourse itself. Such debates have generated extensive reconsideration about the foundation of rights as a social practice.

One implication of this inquiry into who can effectively claim rights is to raise questions about the politics of who grants legal rights. Although sovereign nation states traditionally have been the primary sources of authorized rights construction, administration, and enforcement, historical investigation have made clear that, whether principled or not, dominant groups control who gets rights – when, where, and how much – in practice within national and subnational contexts. Despite the pretenses to general rights entitlement that attend most rule of law systems, ascriptive and tribal standards routinely motivate the powerful to exclude many persons from full rights status. In short, all persons may be said to 'have' equal rights, but how persons are perceived by dominant groups shapes the rights they can in fact enjoy in practice; all rights politics arguably is status politics, to some degree. Moreover, if full rights status entitles disciplined subjects to treatment by liberal legal norms and protocols – including rights to due process, equal protection, property use, political participation, humane and noncoercive treatment, and the like – then those subjects marked as undisciplined, undeserving, or dangerous are doomed to less than full standing as rights-bearers. The latter thus remain vulnerable to more arbitrary, coercive, paternalistic, or even brutal forms of social control. Hence the familiar exercise of legally permissible violence against, or exclusion of, noncitizens, second-class citizens, 'criminals,' and the like for those marked as unqualified for or undeserving of rights in many times and places. And this historical politics of variable rights allocation by dominant groups, both through and beyond nation states, is one of the primary catalysts to the universalistic appeals of human rights that might trump national or local hierarchical power structures.

Do Rights Encourage Atomism, Egoism, and Selfishness?

The contention that rights practices encourage excessive individualism, egoism, and selfishness *among* rights-bearers was perhaps most forcefully articulated by Karl Marx and is commonly asserted by moralists across the political spectrum today. Critics emphasize in particular the tendency of rights to celebrate the individual and thus to undermine citizens' sense of responsibility for their actions, duties to others, and shared commitment or obligations to 'community' (McCann and Scheingold, 2012).

Theorists more favorably disposed to liberal conceptions of rights acknowledge that rights discourses presume, encourage, and protect individuals. Indeed, securing and advancing the exercise of individual citizen capacities for choice, action, self-development, and diversity against the harmful designs of other individuals, social groups, popular majorities, and the state has been the *raison d'être* of rights as a moral concept from the start. At the same time, however, most theorists understand the legal rights of individuals in relational rather than insular terms. Rights practices sustain particular obligations that are reciprocal among citizens as well as a general tolerance and even respect for the human dignity of others. In Kant's (1948: pp. 95–96) famous words, "Act in such a way that you always treat humanity, whether in your own person or in the person of another, always as an end and never simply as a means." Defenders thus argue that, far from undermining a sense of duty, rights support and enforce dutiful interaction among citizens. According to this way of thinking, rights connote a particular vision of community where individual agency and dignity are respected but balanced with conceptions of fairness, justice, and equal treatment for all. It follows that it is precisely the disregard for basic rights that encourages or permits unjust or exclusionary acts that are corrosive of community.

Critical Left theorists have offered insights to this debate. For example, Wendy Brown (1996) and others draw on Karl Marx and Michel Foucault to recognize that the disciplined, normalized subjectivity that is required for legal rights eligibility privileges private pursuits while impeding political dissent that challenges the hierarchical status quo. In short, rights reinforce commitments to private freedom and public deference or apathy. Other theorists (Williams, 1991) recognize that some rights are more self-regarding than others. Marx's powerful indictment, after all, was that it is, specifically, property rights that encourage selfishness, materialism, and competition for dominance through capital ownership. As a consequence, he argued, the positive communal promise of political rights is overwhelmed, thus reducing the promise of political solidarity and equality to an illusion. The underlying point here is that critiques of legal rights that fail to distinguish among different types of rights, within the first generation as well as among the different generations of rights concepts, are unconvincing to many moral and legal theorists. Nevertheless, the claim that rights claiming is selfish and detrimental to the common good or sovereign majority remains an effective political tactic by some

parties seeking to undermine the rights of other persons or groups.

Jurisprudence and Legal Theory

Contemporary discourse on rights within jurisprudence and legal theory is driven by an effort to identify a distinctively legal conception of rights. This discourse is organized around two foundational debates – pitting rights against democracy on the one hand, and natural law against legal positivism on the other. Historically, there have been profound and heated conflicts among the parties to these debates. These disputes are often entangled in other debates over specific policy preferences, over sovereignty when international standards conflict with national authority, and over who is the final arbiter of constitutional, common law, and/or statutory rights – specifically over the role of courts vis-à-vis other state or social actors – within constitutional regimes.

But more recently a rapprochement has developed around the recognition that rights and law are mutually constitutive – that rights without the law are virtually unthinkable, as is law without rights. This convergence not only identifies the core common ground of legal theory, it also reveals the distance that separates the legal theory of rights from the understanding of rights that is found in moral and political philosophy. Whereas philosophical understandings of rights reach well beyond the law in search of universal moral meaning, rights in legal theory are much more constrained – principally by way of the intrinsic connection in legal thought between rights and the institutional processes in which rights under law are embedded. In particular, legal theories of rights seek to specify and to justify the responsibility of courts and judges for resolving disputes over rights, and for policing the boundaries of legitimate rights claiming and recognition.

Legal Rights vs Democracy

The dilemma of legitimating rights claims is especially troublesome to legal officials in democracies and republics, where majority will is understood to carry considerable authority. We noted earlier that legal rights, by their very nature, are intended to protect and advance individual entitlements that restrict the actions of others, including those of popular majorities. As such, rights, both in general and in specific instances, are often condemned as counterdemocratic forces. Utilitarian theorists raise a parallel objection that begins with the assertion that rational public policy should provide the greatest good for the greatest number, thus giving considerable weight to the preferences of the majority. Rights are thus often challenged as costly obstacles to the development of democratic and efficient (see below) social policy.

Other legal theorists respond that rights do not thwart so much as give structure to utilitarian policy calculation, by assigning higher values to certain basic entitlements – especially those concerning protection for individual freedom and dignity – than to other competing considerations. Consequently, securing rights may impose costs on particular social goals, but these costs are arguably incurred in order to sustain larger, enduring social commitments. Likewise, it is argued, rights claims do not absolutely throttle democratic majorities or elected officials; rather, rights claims tend only to place specific, limited restrictions on particular policy actions that defy core social values and protection for individuals. Moreover, it is important to underline that many types of rights advance – indeed, are actually essential to – the democratic process. Such entitlements include, at the least, protections for dissenting speech, political association, free elections, due process, and basic public education. There is no simple way out of this debate. Although it may well be true that rights in general provide sustenance to democratic polities, particular rights constructions certainly do, and indeed are intended to, defy the will of elected officials and popular majorities. Hence the enduring challenge for judicial authorities is to justify by legal argument their specific rights constructions.

Rights and Justice

Historically, a divisive debate in legal theory between positivism and natural law has pitted a theory of law that recognizes little in common between morality and law against a conception of law as being inseparable from morality. The latter is virtually indistinguishable from the moral philosophy of rights discussed earlier, and represented by the work of Locke and Kant, among others. The former is rooted in analytic philosophy and in a logical positivism that eschewed the search for universal truths. During the late twentieth century, the gap between legal positivists and natural law theorists narrowed (but was by no means closed) by the emergence of a widespread agreement on a least-common-denominator conception of justice as the 'right to have rights.' According to this way of thinking, the guarantees associated with rights are confined to assuring predictability, reciprocity, and impartiality in the application of the law. What remains unresolved in the debate between theorists of natural law and legal positivism is whether justice, as thus defined, is the differentiating element of legal right, or only a quality that tends to be closely associated with legal rights.

Although many jurists have not reached out to the broader realms of political and moral philosophy, Ronald Dworkin (1977), one of the most prominent twentieth-century legal theorists of rights, has done so. At the core of his analysis is the distinction between policy and principle. Whereas policy is driven by utility, principle – the defining element of law – should be observed not because it will advance or secure an economic, political, or other situation deemed desirable, but because it is a requirement of justice, fairness, or some other dimension of morality. In thus linking law to principle, and principle to justice, Dworkin identifies himself with the relatively noncontroversial common ground between positivism and (neo)natural law. On the other hand, by introducing some other dimension of morality he clearly broke new ground. For Dworkin, constitutions and constitutional rights "fuse legal and moral issues" (Dworkin, 1977: p. 185). Constitutions thus provide not only the right to have rights, but particular substantive rights as well.

For Dworkin, then, rights are inextricably linked not only to the foundational elements of positive law, but also, at least in their political and constitutional incarnation, to the foundational elements of the state. In this sense Dworkin can be seen

as a kind of transitional figure among legal theorists, reaching out as he does to moral and political philosophy and incorporating them into his analysis of rights constructions by judges and other state officials. But unlike the theories of moral and political philosophers, Dworkin's theory of rights is embedded in, and inextricably linked via principle to, what is distinctively legal. Moral philosophy thus becomes an adjunct to the law and is, in effect, put at the disposal of the law, as a source of principle. In this sense, Dworkin's theory of rights returns to the starting point and indeed to the cornerstone of jurisprudence and legal theory; that is, it is a search for what is uniquely legal, as opposed to moral, ethical, or political.

Empirical Social Science Studies of Rights Practice

Whereas philosophic and jurisprudential inquiries into rights tend to be normative and abstract, social science research regarding rights practices is explanatory and empirical, although it is often informed by questions from critical social theory. Generally speaking, in the social sciences, legal rights are treated less as predictable, state-authorized entitlements of historical persons than as contingent resources that are mobilized both by individuals in everyday life and by organized interests in political advocacy. Rights are not viewed as 'above politics' and power so much as constitutive of political activity and power relations. The primary objective of the social sciences thus is to assess the value of legal rights as resources, and to explain variations in how rights work and to what effect in different sociopolitical contexts. To do so, social scientists shift the locus of rights inquiry from formal systems of logic and idealized institutions to inductively organized research on legal rights as practices in actual institutional settings, everyday life, and political advocacy.

Rights and Everyday Disputing

There has been a rapidly expanding scholarly literature on the ordinary disputing practices of citizens, especially in the United States but increasingly around the world. Many studies of 'ordinary' (non-elite) individual citizens in the United States suggest that rights matter a great deal, and that these individuals are not hesitant to assert them. Indeed, some scholars demonstrate that lay people, more so than judges, clerks, police, and other legal authorities, act on the premise and the expectation that the legal system exists to protect rights. One of the most interesting findings of Ewick and Silbey (1998) is that ordinary, non-elite citizens in the United States can relate to rights in flexible, creative, and complex ways, entertaining several conflicting notions at once. Interviewees in their study could view rights instrumentally as malleable rules of a game, authoritatively as an objective source of valid law, and skeptically as a burden that must be endured, evaded, or resisted.

Other studies qualify or challenge assumptions about the salience of legal rights. Research on the disputes of individuals suggests, for example, that Americans and others often refrain from asserting their rights; many studies document a widespread reluctance to seek formal redress from the state or other authoritative institutions when rights are violated and entitlements denied. This is especially the case among lower-income and minority citizens. Moreover, some studies offer evidence of considerable cultural biases and popular pressure against rights claiming, at least through formal adversarial channels, even in allegedly 'rights-obsessed cultures such as the United States. Moreover, much sociolegal studies question whether most citizens are as beguiled by what Scheingold famously labeled the "myth of rights" – the promise that legal institutions protect and enforce inherited rights for all persons – as once was believed (Lovell, 2012). Patterns of individual rights practices thus tend to be complex, contradictory, and context specific.

Studies into everyday rights construction and practices beyond the US context have proliferated in recent years. On the one hand, there is much evidence that legal rights talk and engagement is growing in many places around the globe, including in contexts of Islamic faith (Osanloo, 2009) and much of the global South (Wright-Carozza, 2003). On the other hand, much evidence suggests that citizens in many contexts with well-established constitutional mechanisms are reluctant to claim rights even when they have legitimate legal grievances about harm or neglect (Atuahene, unpublished). Especially relevant in this regard is Engel's admonition, grounded in his rich empirical study of provincial communities in Thailand, that increasing diffusion of rights discourse among cosmopolitan elites is often not shared by many ordinary people (2012). As Engel encourages, we need much more study of ordinary disputing and relationships in varying contexts to understand how much (or how little) the diffusion of human rights has mattered in practical affairs.

The Politics of Rights: Mobilizing Rights in Political Advocacy

The value of legal rights as a political resource for challenging hierarchy and injustice is heavily debated within the social science literature. The most stringent critics of rights strategies claim that to deploy rights is at best ineffectual, and at worst counterproductive. Some studies suggest that rights litigation has no more than negligible effect on policy outcomes. According to realist critics, only political power built around electoral coalitions and influential interests can bring about changes in well-established legal policies and practices. Other scholars demonstrate that rights-based practices often do intrude into policy processes, but with the unfortunate consequence of making these processes rigid and inefficient. And some empirical studies show that human rights discourse promotes illusionary promises of freedom that divert attention from fundamental transformations in hierarchical power relations (Englund, 2006).

There is, however, a substantial body of research that suggests rights strategies can make meaningful contributions to a transformative politics, albeit in complex, contingent, and unpredictable ways. This research does not so much invalidate the findings of critics as shift the focus and the standards by which rights strategies are to be judged. Instead of concentrating exclusively on the direct effects of court-articulated rights, the indirect and constitutive effects of rights-based action are explored and assessed. Moreover, in this research, the criterion for judging rights strategies shifts from policy efficiency to social equity and empowerment, with the salience of this latter criterion most compellingly articulated in the work of critical race and critical gender theorists. Especially in the

United States, where much of the available research has been conducted, the indirect and transformative potential of a 'politics of rights' (Scheingold, 1974) has been persuasively demonstrated. Just as rights have a constitutive impact on individual disputants, so too have the connotations of entitlement associated with legal rights had a mobilizing impact on social movements for minority inclusion, women's rights, pay equity, disability rights, and animal rights. Insofar as a need or a grievance can be articulated as a legal or constitutional right, expectations can be altered, quiescence overcome, and a politics of rights generated. Note that this research focuses very much on the discursive power of legal rights to constitute social and political life. Moreover, despite their liberal connotations and associations, rights can also be deployed on behalf of substantive agendas that span the political spectrum (Santos and Rodriguez-Garavito, 2005).

Despite all of their persuasive power, however, most scholars agree that rights claiming alone ensures very little transformative power. Nor is rights mobilization a matter of spontaneous combustion. The constitutive power of legal rights depends on deploying rights shrewdly, in conjunction with other political resources, including shrewd leadership and legal 'support networks' (Epp, 1998) working in combination with established organizations like churches and other religious associations, labor unions, NGO advocacy teams, and other kinds of social-action organizations (McCann, 1994). Even then a transformative politics does not necessarily follow. Political mobilization may, for example, generate effective countermobilization by rival or dominant groups. But as the struggles over abortion in the United States and gender violence in many parts of the world demonstrate, rights can matter, and a well-executed strategy of rights can at the very least destabilize the political arena, thus creating opportunities that were previously foreclosed. In sum, the increasing body of empirical research on rights advocacy in a variety of settings underscores the variable, contingent, and often-contradictory implications of a politics of rights (Santos and Rodriguez-Garavito, 2005).

Risk and Uncertainty in the Social Sciences: Implications for Social Work Theory and Practice

Tim Blackman, The Open University, Milton Keynes, UK

Abstract

Uncertainty is one of the few certainties about policy and professional practice in social work, where knowledge is often imperfect and contested. Virtually every decision takes place in a context of some degree of uncertainty. This article explores differing sociological approaches to uncertainty and risk, and considers what these mean for evidence-based practice. It offers applied examples from the areas of child abuse, violence, and dementia to illustrate contemporary approaches to managing uncertainty and risk.

Sociological Approaches to Uncertainty and Risk

Uncertainty, whether due to 'known unknowns' or 'unknown unknowns,' is one of the few certainties about policy making and professional practice. Virtually every decision takes place in a context of some degree of uncertainty and therefore entails risk.

Risk is often described as having two dimensions: probability and impact (Fischhoff and Kadvany, 2011; Zinn, 2008). In risk management practice, the representation of risk along these two dimensions often uses scales such as unlikely/likely/certain for probability and negligible/moderate/critical for impact. Responses are then formulated and estimates made of how far these reduce the probability and impact of each risk. Representing risk in this way is common practice (Cabinet Office, 2010; Hopkin, 2012). However, it can create the impression of having more certainty than justified. Descriptors such as 'likely' and 'unlikely' have been shown to elicit different meanings for different people. Scores rather than descriptors are sometimes used but can give an illusory precision. Even if there is a sound basis for quantifying risk, how this is represented can alter its perception (O'Hagan et al., 2006). Lacking personal control over a risk or being unfamiliar with it generally heightens sensitivity to risk (Taylor-Gooby and Zinn, 2006). As we consider later, this is one reason why governments may overreact to risk by imposing audit and control regimes on the practice of care professionals.

In professional practice, risk is about managing uncertainty. If a risk of danger or harm materializes – nonaccidental injury to a child, for example – then professionals involved in safeguarding children are expected to account for their actions. However, by definition, in a world of probabilities the improbable does happen. Even if we can calculate how unlikely it is, doing the 'right' thing is no guarantee of a successful outcome. Similarly, a successful outcome may have nothing to do with doing the 'right' thing. Uncertainty and risk are far more than just knowledge problems in a positivist sense that the facts are 'there' to guide action, if only we can know what they are. Even psychological knowledge of how interpretations of facts are affected by preconceptions suggests there is a single reality about which we could be certain if we fully understood it, and that may not be the case.

Sociological approaches to risk and uncertainty question the notion of a single reality: that knowledge is a given with which everyone will agree as long as they have the facts, even probabilistic facts (statistical predictions from prior facts). Incomplete knowledge is often blamed for failures in care services, such as key information about a vulnerable person not being passed between agencies. This has seen responses to improve information sharing and communication across agencies and services, but these can easily stall if there are different interpretations of 'facts.' There may, for example, be very different constructions of 'harm' and 'abuse' across professional fields of practice and different cultures (Bowes and Daniel, 2010).

This is not just a question of different constructions but also, fundamentally, of discourse. Discourses are ways of thinking, communicating, and acting that impute meanings and serve particular interests. A discourse approach treats phenomena as imbued with subjective notions and shaped by social relations, especially relations of unequal power (Tulloch and Lupton, 2003). Who, for example, decides an issue is a risk? To what extent are decisions made by those affected, or made for them? How constrained are the options, who bears the risk, who decides what to do, and with what accountability?

These issues can be investigated using social theory. Macro-theory is about societies as a whole, and at this level theories of uncertainty and risk can give a perspective beyond everyday understandings and draw attention to how risk and uncertainty are manufactured by the kind of society in which people live. Middle-range theory, on the other hand, is more concerned with explaining outcomes at local or organizational level, where it can assist practical decision making. This theory can help to explain why an outcome is to be expected, or why it does not happen, such as the 'if … then' reasoning that is used to construct what are known as 'theories of change' for the purpose of evaluating interventions (Pawson and Tilley, 1997).

We will first explore some macro-theory approaches.

Risk Society: Risk as a New External Condition

German sociologist Ulrich Beck looked to new social movements in the 1990s as a way to understand 'late modernity'

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28097-5

(Beck, 1992). Beck argues that Western societies have transitioned from a dominance of tradition shaping daily lives and routines to a dominant conception of autonomous individuals freed from tradition. During much of modernity there was an orientation to progress, associated with the growth of welfare states and consumer societies, but in late modernity public concerns have turned to risk as anxieties have grown with the loss of traditional reference points and the rise of new risks borne out of modernization itself.

Rather than being empowered by what might be seen as a new freedom to decide for yourself in modern societies, Beck's argument is that people in the West have become ever more conscious of risk. This is due to the certainties of traditional beliefs having been lost and the unavoidability of having to make decisions. Decisions involve risks and, increasingly Beck argues, these risks appear harder to calculate and manage. This is because there is a new type of risk in late modern societies: nebulous, large scale, and very dangerous, created by societies themselves as individualization drives economic growth, new technologies, and social change, from global warming to family breakdown (Stalker, 2003).

In choosing social movements as his main object of study, Beck's theory took shape in a particular way, emphasizing global environmental risks. His theory is also realist: he considers that he is dealing with an objective external reality, albeit potentially interpreted in different ways. The opposite perspective, constructivism, argues that reality is entirely socially constructed and self-referential rather than externally referenced, with no single theory or explanation possible without recognizing this as relative and contestable from a different standpoint (Dybicz, 2011; Garrett, 2013; Houston, 2001).

Teenage pregnancy, for example, is a construction in these terms. It is often constructed as a 'risk' to be avoided, needing intervention with social programmes because of evidence of relatively poor outcomes for both mothers and babies, but may be constructed quite differently by mothers themselves buoyed by the experience of having a baby to love and care for (Duncan, 2007; Graham and McDermott, 2005). Social scientists have also argued that risk in teenage pregnancy is a consequence of social inequality rather than motherhood, although with a range of views from there being nothing intrinsically 'wrong' with teenage motherhood to it being a 'choice' made in the face of no positive alternatives (Harden et al., 2009).

Constructivism is sometimes parodied as an 'anything goes' theory that opens the door to all kinds of positions and beliefs with no means to decide between them, but its main contribution has been to oppose all-embracing grand theory. This is a theory that fits every social phenomenon to explanations of one kind, such as that all people are rational and narrowly self-interested actors (as in rational choice theory) or society's relationships and ideas are determined by economic forces (such as in structural Marxism) (Ritzer, 2003).

Beck's work is certainly macro-theory and has been criticized for its degree of generalization, but his interest in social movements was substantially because they opposed the 'rationality' that drives new, environmentally damaging technologies. These movements are cultural phenomena not explainable as class struggle in orthodox Marxist terms but, nevertheless, a force in society.

Beck, though, was most definitely not part of the cultural turn that saw much of the social sciences in the 1980s and 1990s shift to a relativist paradigm of constructivism. His analysis is offered as 'right' because it is argued as the best possible knowledge of what has been happening in society. However, terms such as 'right,' 'wrong,' and 'choice' are loaded with overtones and connotations. Who is to say what knowledge is right or wrong, or that a choice with its attendant risk is a real or forced choice? Who is responsible for a baby failing to thrive: the teenage mother, the preventative services that failed to intervene successfully, or the society that allows the obvious deprivation that makes it so much more likely that the teenage mother is poor? (Stalker, 2003).

This brings us to the second well-known theory of risk and uncertainty: governmentality.

Governmentality: Risk As a New Internal Condition

Governmentality is a concept from the French social theorist Michel Foucault's work on power and discourse (Foucault, 1991). While Beck emphasizes the mass protest and alternative movements that have mobilized against the risks of late modernity, governmentality sees attitudes to risk as embedded in the norms and practices of society, so that conformity is encouraged and nonconformity stigmatized and even demonized.

Governmentality is about how people become governed by internalizing the instrumental purposes of governing elites into their own subjective rationalities and self-conduct. The 'right' decisions are reinforced and rewarded psychologically by affirming norms, such as young people delaying childbirth until economically self-supporting. Deviant behaviors are constructed as 'other' and dangerous because they infringe the social rules on which social order depends, labeled by pejorative terms such as 'welfare dependency' (Spicker, 2008).

This is most obvious in power strategies that aim to change people's behavior directly, however well intentioned, such as compulsory education and mandatory pension schemes, or outlawing smoking and drinking alcohol in public areas. Risk is a fundamental justification for these strategies. But it is not always governments that pursue them: recently, there has been a rise of 'technologies of the self.' An example is Google Now, a type of virtual personal assistant that anticipates personal information needs based on what Google already knows about you. The latest version reports each month how many miles you have walked or cycled, a type of ethical surveillance ('walking and cycling are good for you') that would probably see protests on the street if it was government surveillance. Yet, "with Google at the helm … resistance is minimal. We don't mind our phones spying on us …" (Morozov, 2012).

Of course, delivering and sharing information via mobile phones, increasingly with easy-to-use applications, may be empowering. Harvesting data from these interactions can also be used to predict, prompt, and recommend in useful ways. But an important feature of technologies of the self is the role of expertise in allaying anxiety about risk: "… expertise operated not through social planning, paternalism and bureaucracy, but in terms of a logic of choice … through inculcating desires for self-development that expertise itself can guide" (Rose, 1999: p. 88).

It is possible to see 'expertise' at work in a further aspect of modern society, that of calculative practice, or the identification of groups in the population with risk characteristics, increasingly termed 'predictive analytics' (Siegel, 2013). Examples range from setting insurance premiums to preventative social programs. While these approaches can be helpful, a potential problem is the uncertainty that surrounds calculations often based on population averages and relative likelihoods. This means there is a risk of false positives and false negatives: the models may either label an individual or family as needing intervention when this is not the case, or fail to identify someone needing help. Care professionals are often wary of these approaches since it is the individual case they happen to be working with that matters – whether that is a person, family, or community – and not managing people as statistical categories.

Predictive analytics works with variables, modeling relationships in a statistical space where the variables are disembodied from actual cases (so an 'average' case, for example, may be rare or nonexistent when nonaverageness is typical). To the extent that predictions work, it is because they capture a combination of circumstances in people's lives. What is important is not a statistical calculation but being able to recognize a qualitative state or set of conditions that, by combining, cause an emergent outcome. Understanding the 'why' of this causation needs tacit, intuitive, and formal knowledge of each case and context, reaching shared understandings that aim to recognize the conditions that matter and intervene to change them (Blackman, 2013).

Evidence, however, is just one of multiple streams into policy action and is rarely, if ever, unfiltered by bureaucratic, business, and political interests and considerations. We now turn to illustrate this with examples from child and domestic abuse.

Managing Abuse and Violence

A desire by the public and politicians for care professionals to have certainty and 'omnicompetence' has been evident in a range of domains but one of the most high profile areas has been social work with children who are considered to be suffering from abuse. Gilbert et al. (2011) conducted a review of developments in 10 countries (an exercise first conducted over a decade before) and noted that there had been a broadening in definitions of risk. This had been accompanied by an expansion in the numbers of children and families referred to statutory services and in receipt of services, and of children placed away from home. Developments in all 10 countries demonstrated an increase in the formal procedures regulating child protection work. A key development was that across the countries surveyed, a range of different tools and technologies had been introduced to make front-line professionals in particular more formally accountable for what they did and how they did it. This increase was evident in countries with very different welfare regimes (e.g., the United States, Germany, and Norway) and differing histories of operating along the continuum of supporting-controlling families.

Smith (2001) has explored the literature on confidence and trust in order to understand the implications of the growth in accountability measures. She notes an important distinction between confidence and trust. Confidence refers to the general sense of safety and reliability that we invest in systems, which includes having certain expectations in relation to professional roles and the regulatory frameworks governing these systems. Thus, in relation to child care services, confidence would refer to the qualifications of those working in the system, expectations about their role, and expectations about the frameworks concerning the regulation and inspection of what they do.

Trust serves as a guide to interpersonal relationships where the outcome cannot be guaranteed and, indeed, where the possibilities of disappointment and regret are always present. If activities such as social work are to be really meaningful in the sense of bringing about positive outcomes in people's lives, then trust is crucial for the following reasons. First, many of those who need services will have experienced situations where their trust was betrayed very profoundly. This might lead to the conclusion that it is better, therefore, to concentrate on developing systems based upon rights and entitlements. While rights are a vital underpinning for services, they are exercised in interpersonal encounters: services, including those based upon rights, are mediated by people. Research evidence suggests that how a service is delivered really matters in terms of whether people continue to access it. For example, young people constantly give feedback on the importance of how they are talked to by workers and whether they feel such workers are genuine or not (Featherstone and Evans, 2004). Secondly, developing a trusting relationship with another can help repair the damage that has been done by earlier disappointing relationships. Furthermore, social workers can demonstrate that to trust is not always foolish and that change is possible.

Trust and confidence are related but not the same and, moreover, systems that are only focused upon confidence building can destroy the possibilities for developing the kind of trusting relationships we have described above. Under many of the audit arrangements set up to make child protection more accountable, such as those introduced by governments in England over the decade from the late 1990s, strict guidelines were set down on how long it should take to do an assessment and how the assessment should be carried out, using prescriptive computerized programs. However, ethnographic research found a key casualty of this approach that was the amount of time spent in face-to face contact with service users. Researchers demonstrated that the audit tail was well and truly wagging the practice dog as social workers prioritized inputting data into computers over visiting families and spending time with them in order to explore uncertain and fluid situations (White et al., 2010). Moreover, it became apparent that too much attention was paid to measuring the time it took to do certain tasks but not to exploring how the task was done.

How the task is done is crucial. It is important to be able to measure how many children attend the meetings that are held to discuss their care, but it is just as important, if not more so, to devise meaningful measures that assess their level of participation and how they feel about the quality of those meetings. It may be in these circumstances that simply designing more and more individualized performance measures is not the answer, but rather developing good quality, well-resourced consultation mechanisms with children and young people.

The implications for practitioners of an agenda with its focus on standardization, e-technology and performance management was to receive sustained critical scrutiny in the wake of the death of baby Peter Connelly in Haringey, London in 2007, as research evidence emerged of social workers tethered to their computer stations with direct contact with families a precarious, time limited project. A government commissioned review by Professor Eileen Munro urged a paradigm shift from a risk averse to a risk sensible approach and, in that context, the promotion of practices that involve the exercise of professional judgment rather than compliance with prescription (Munro, 2011). She noted the importance of recognizing that risk can never be eliminated, that uncertainty lies at the heart of human existence and that, when deaths happen, it is not always the case that someone is to blame. It is not possible to know for sure what is going on in the privacy of family life, nor can we predict with certainty what will happen. A fundamental change needed was realistic expectations of how well professionals can protect children and young people.

Munro (2011) concluded that the demands of bureaucracy had reduced practitioner capacity to work directly with children, young people, and families. Services had become so standardized that they did not provide the required range of responses to the variety of need presented. She urged the importance of moving from a compliance culture to a learning culture. She also recommended that services be redesigned using 'sociotechnical' principles, with due attention to the role of professional judgment. Such established principles have been used to good effect in health care systems, exemplified in the patient safety movement (Wachter, 2010).

The review built upon and promoted an interest in thinking about the role of systems design in supporting practitioners in areas where human judgments have to be made, where certainty is absent and the stakes are high. An examination of the literature on human factors in decision making shows that the intrinsic characteristics of information processing by human beings operate as both friend and foe in social work decision making (White, 2009; White et al., 2010). At an individual level, human beings are equipped with an innate apparatus to assess our fellow human beings on an intuitive and emotional level, and alongside this we have particular cognitive biases. The generation of hypotheses about situations is affected by our cognitive capacities in two principal ways: it is limited by what is available in memory and by 'psychological commitment' to the first hypothesis. This is confounded by the related tendency to seek out evidence that confirms a hypothesis, rather than searching for disconfirming evidence. Thus, once we have settled on an interpretation of events we tend to deviate little from our initial hypothesis. When we add to the equation the social, psychological, and sociological dimensions, which generate powerfully normative cultural practices, we have a heady cocktail indeed (White, 2009). Practitioners need to have the time, space, argumentative flexibility, analytic ability, and trusting relationships to debate and make sense of what is seen and recorded (Featherstone et al., 2012b).

Current developments in policy and practice underscore the difficulties of embracing uncertainty and the ubiquity of the search for certainty (Featherstone et al., 2012b). Child welfare policies in relation to early intervention are increasingly underpinned by a neuroscientific argument, which has been widely critiqued from within neuroscience itself but is often unchallenged in current policies (Wastell and White, 2012). Read carefully, the original neuroscience literature shows that the infant brain has quite remarkable resilience and plasticity when exposed to ordinary patterns of 'chaotic' neglect usually seen in the population referred to children's social care services. If changes to the brain were the criterion for removal from parents, very few children would be removed. Yet, the rhetorical potency of the 'now or never' argument is so great that it is supporting a drive toward early removal of children from their parents and has become a powerful professional mantra in England.

Many, if not most, of the measures introduced in child protection over recent decades are central to more 'top-down' attempts to ensure certainty in an area subject to public scrutiny. However, it is instructive to look at another area, that of working with men who are domestically violent, to see 'bottom up' demands for certainty. Here the imperative appears linked to historic concerns about women's and children's safety and the best way of ensuring such safety.

There is a considerable history of developing programs that work with men who are violent to women in intimate relationships (Rivett, 2010). These have usually been called perpetrator programs and have their roots in both the therapeutic, antisexist men's movement and the women's refuge movement in the United States (Featherstone et al., 2007). Historically, it is the latter that emerged to set standards for treatment and safety as a result of concerns that those which had a more therapeutic focus were in danger of excusing men's behavior. Moreover, they were considered to be too isolated from mainstream services and, therefore, unable to ensure the safety of women and children. The Duluth program emerged over time as the foremost program reflecting a feminist perspective on the causes of violence as rooted in men's control and power over women in a patriarchal society and masculine socialization practices. It had its origins in community reaction to the murder of a woman in a specific area in the United States.

Currently, programs consist of a set format where power, control, and equality issues are systematically addressed and where cognitive-behavioral therapies are used. This is the model that has been supported by UK governmental guidance and is the regulated program for criminal justice settings. Practitioners within the field have created a charity called Respect to lay down standards of good practice and to accreditation.

Over the years, Duluth programs have been subject to a number of criticisms. Their set format is considered to be too prescriptive and insufficiently sensitive to the differing needs of men attending them (Rivett, 2010). An allied critique has contested the underlying theoretical approach as it assumes singular explanations for why men are violent and relies on cognitive-behavioral approaches. Some have argued for psychosocial approaches that engage with unresolved childhood pain and trauma. A range of writers have suggested the importance of recognizing that not all violent men are the same and that not all violence is the same. Moreover, it is argued that the role played by factors such as mental health difficulties and

substance misuse need more consideration than that found in Duluth. However, contemporary debates reveal considerable anxieties about moving away from a set format (Featherstone and Fraser, 2012). The tensions and anxieties here are linked to long-standing debates within feminist and profeminist scholarship and practice, and the continued difficulties with moving away from dichotomizing and splitting, especially in relation to understanding and working with men's violence. Singular explanations and approaches seem to offer certainty in a field where engaging with diversity and complexity has been equated with excusing men's violence and therefore jeopardizing women's safety. The evidence base remains underdeveloped, and there is not a straightforward recourse to evidence to settle arguments.

Evidence-Based Practice

The 'objectivity' of predictive models is attractive when it comes to legitimizing a professional decision for which an individual practitioner may be held to account and asked for more justification than intuition or tacit know-how. Calculative technology brings risk into being and creates types of risk discourse, notably that of 'evidence-based practice.' The promise of evidence-based practice has been to create and act upon explicit knowledge for doing the right things right, based on robust findings from rigorous research, which has usually meant quantitative research because of its claims to reliability and generalizability (Blackman, 2013). The cultural approach of many valid types of knowledge and rationality means that every decision is a risk because an optimal decision is impossible without objective reference points. Evidence-based practice holds the promise of a single rationality where risk is at worst a calculated risk.

The complexity of the social world and human behavior often confound this approach. There is simply not enough knowledge to understand what will happen when intervening in complex, context-specific situations that research designs such as randomized controlled trials struggle to simulate. We have noted this complexity already with our examples of child protection and domestic violence. Another example is dementia care: what can an aspiring evidence-based practitioner make of the following account of what we understand about dementia wandering?

> (T)he same behaviour or type of wandering might occur for different reasons in different individuals; any theoretical formulation is going to have to allow for different triggers for the behaviour and so to get a "one size fits all" kind of explanation is unlikely. (Hermans et al., 2007)

The danger with this kind of uncertainty is that we resort to risk minimization, such as keeping people with dementia indoors and 'safe.' Dementia is still often constructed as an illness rather than a disability (Loveday, 2013). If framed as a disability, the focus is commonly on the impaired individual rather than the risks created by their environment or the behavior of others around them. Knowing the person and how they interact with the world around them is the route to understanding what is 'right' in a given set of circumstances, discussed and agreed between all parties, and in fact few decisions can be based on the generalizations and predictions of quantitative research. At best, all that may be available is trial and error as different approaches are tried out.

This chimes with the views of many advocates of qualitative methods, but while the case-based approaches of qualitative research with their rich descriptions can often give insight into *how* something happens, they are much more limited in answering *why* questions because these need a systematic comparison of cases. Methods are available for doing this, such as qualitative comparative analysis, which groups cases into sets of common attributes associated with particular outcomes (Ragin, 2000). The method handles situations such as the same outcome resulting from different combinations of conditions, or a condition having different effects depending on its combination with other conditions. This recognizes interaction, contingency, and complexity, which conventional quantitative research often fails to do (Blackman, 2013).

Conclusion

While the cultural turn in the social sciences has been important in emphasizing subjectivity and the different rationalities by which people live their lives, its relativism is a problem for policy makers and practitioners who need to make decisions. The cultural approach encourages empathy and self-reflexivity, raising awareness among practitioners about their own position in relationships of power, and their influence on how 'reality' is constructed through the influence of their own experiences and involvement. But practitioners and those they work with also need evidence on which to base whether to do (a) or (b), and these are often binary decisions. However rich the narrative of a qualitative study or specific a statistical probability or correlation, the evidence needed is middle-range theory that can isolate, as well as possible, a few explanatory factors that explain important but bounded aspects of why an outcome is to be expected or risk managed.

This is the approach we see with realistic evaluation, based on developing theories of change (Pawson and Tilley, 1997). These set out what is thought needs to happen to achieve the outcome aimed at. If the theory is right, the outcome and intermediate signs on the way to it will be as expected. If it is wrong, the learning is recycled back to improve the theory. The approach does not solve the dilemmas and challenges posed by macro-theories such as risk society and governmentality. These remain important for the critical and reflexive thinking about practice they engender. But it does support logical 'if … then' reasoning about outcomes from intervention that makes expectations explicit. Policy and practice are not technical exercises but complex blends of facts, interpretations, opinions, and evaluations (Majone, 1989). Yet, assessments and decisions need to be articulated explicitly if learning is to be possible.

Risk Assessment in Social Work

Marilyn Callahan, School of Social Work, University of Victoria, Victoria, BC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Risk is a ubiquitous concept used in social work and other professions, most frequently meaning the chance of reducing negative occurrences in the future. Other definitions of risk and interrogations about the impact of its use in social work are infrequent, in particular its connections with neoliberal reformation of welfare state policies and programs. Instead, assessing and managing risk has become a central activity in social work, in particular the fields of child welfare, corrections, and community care. The unintended consequences of adopting risk as a core concept in social work are explored and alternative ways of thinking based on social work principles are provided.

Introduction

The promise of risk is a compelling one. If social workers can identify individuals who are 'at risk' of having bad things happen to them or of doing harm to others then they can focus their helping efforts where they can do the most good. They can justify intruding on the lives of certain individuals even if they have not sought help because they are preventing problems from occurring.

These two dilemmas, how to be trusted helpers for individuals in need and yet at the same time serve as agents of social control, and how to move from being professionals who mop up problems after they have occurred rather than working to prevent them from happening in the first place, have bedeviled social work since its inception. It is no wonder that when risk assessment and risk management imbued the thinking of business, government, the environmental movement, and the professions during the last two decades, social work was quick to join forces.

The intent of this article is to scrutinize this promise. After years of hard work spent refining risk assessment tools and risk management approaches, have risk and the attendant practices associated with it lived up to its early expectations?

The Complexities of Risk

From the outset, risk is a tricky concept to define. Although a taken-for-granted term used in common parlance, the various and sometimes contradictory meanings of risk and theories about its function in modern society have inspired protracted debates. In many ways, its present usage, as a calculation of what could happen in the future, can be dated at least from the Renaissance and the discovery of probability laws. These laws represented a challenge to superstitious and religious explanations for seemingly random events and offered a more scientific understanding (Bernstein, 1996; Covella and Mumpower, 1995). Risk is thought to be one of the key concepts defining modernity, not just in the hope that it can bring rational understanding to apparently irrational events but its promise to predict future disasters largely based on past experience and mitigate them by controlling present behavior. Hurricane Sandy, the devastating storm that struck Manhattan and the eastern seaboard of the US in 2012, demonstrates the distance that still must be traveled between predicting disasters and managing them, if indeed this is ever possible.

Risk has always contained positive connotations. In some cases, it is similar to bravery, as in the shrewd investor who takes a calculated risk or chance to maximize his profits or the gold medal alpine skier who attains highest speeds and therefore takes the greatest risks. In this sense, taking risks is necessary to succeed. Most commonly, however, risk continues to be associated with danger and disaster, as even for those who take risks, tragedy is a distinct possibility. And eschewing risk is most often recommended. For instance, physicians tell us to reduce our weight to avoid the risk of heart disease, investment counselors tell us to put aside money for retirement to avoid the risk of poverty in old age, and weather forecasters tell us to leave our homes in the face of a storm. In fact the deluge of risk warnings, often contradictory, has sometimes weakened the credibility of the scientific knowledge and professional credibility. Yet, the power of risk remains in spite of these setbacks. Prudence in personal and organizational behavior is applauded.

Social work has similarly embraced a risk avoidance approach particularly in those fields where it is charged with protecting vulnerable individuals and those around them. The profession may be becoming so 'risk-adverse' that it is losing its autonomy and commitment to change (Changing Lives, 2006). However, among the many factors reinforcing this commitment to risk avoidance is 'the duty of care' ethos (Granich, 2012), whereby social workers make ethical commitments "to avoid acts or omissions which one can reasonably foresee would be likely to injure another; also, the duty of people in particular circumstances and occupations to protect and control others" (Australian Association of Social Workers Code of Ethics, 1999: 26).

The opening paragraph in a recent article is typical of the casual way risk language permeates social work discourses.

> Research suggests that when fathers are positively involved in the care of their children (e.g., by providing emotional support, appropriate discipline, supervision), the risk of negative youth behaviours such as delinquency are reduced. Conversely, when fathers are negatively involved with family members (i.e., substance abuse,

> mental health problems, intimate partner violence), there is increased risk of harm to the children in the home.
> Nutton, 2012, http://www.mcgill.ca/crcf/projects/researchwatch

The choice to examine fathers' behavior, its variability across temporal periods, classes and cultures, the quality of the science suggesting a link to future behavior of children, and the impact of this research on fathers and social workers, are left unexplored in these few sentences, as if such questions are unnecessary. Yet, at the core of the commitment to risk thinking is the longing to have a more scientific basis to social work practice. It is assumed that risk factors connecting one occurrence to another have been identified through rigorous research yet the existence and quality of that research may be unexamined. The ideology that rests behind these assertions is also unexplored.

The dominance of risk thinking in social work and other professions as a reflection of ideological imperatives is the subject of much theorizing. Kelly (2001) traces the connections between globalizing tendencies toward economic growth and exploitation of new global markets and the restructuring of liberal welfare governments. Neoliberalism, the political approach taken to support this direction, focuses upon facilitating the global movement of capital and producing wealth, at least for some. These goals are given priority over support and assistance to people 'in need,' and require that these individuals decrease their demands on the state and simultaneously increase their activities as producers and consumers in service to economic growth.

Rose (1996) has theorized 'risk' as one of the organizing concepts of this shift in governing. Reacting against welfare state policies, which they claim, drives budget deficits and high taxes, neoliberal regimes typically focus on shifting attention away from notions of individual need and social problems. Instead, the organizing concept of risk is used, focusing on possible future harms that individuals themselves must address, while the new task of governments is to create smaller 'risk classes' requiring state support (Rosanvallon, 2000). This fundamental shift in thinking replaces 'need' with 'risk' as the organizing concept for services.

The primary administrative strategy for accomplishing the shift from welfare state to the neoliberal agenda has been referred to as 'new managerialism,' an approach well summarized by Tsui and Cheung (2004). They list eight features of new managerial strategies, including a strong focus on the market rather than society or community; efficiency rather than effectiveness as the main criterion of success; money and contracts rather than care and concern as the 'foundation' of relationships; and standardization as the measure of quality in service provision. In this scenario, professional knowledge is subordinate to managerial knowledge, and professionals themselves are less important, since managers can carry out required tasks through delegation and standardized controls.

While neoliberal ideas have faced some challenges in recent years, their basic beliefs and legacy of managerialism remain influential in shaping human services. Good organizations are deemed to be those that adhere to sound business practices and risk management, even as the vast differences between helping individuals and making money continue uncontested.

The environmental movement has picked up this focus on risk and used it to great advantage in advancing its aims. Since 1972 when a Greenpeace mission successfully stopped nuclear testing on Amchitka Island in Alaska, environmental activists have successfully drawn attention to significant risks to the environment. Using the power of an increasingly sophisticated science and using measuring tools such as risk assessments, they have changed the way much of development now occurs and, in the process, brought credibility to the concept of risk and its importance for policy-making. Many social workers are sympathetic to the aims of the environmental movement and admire its methods.

This brief discussion of risk, a topic that has generated a great deal of theorizing, nonetheless underscores several contradictions inherent in the concept that are central to social work. The issue of risk and choice is important. Accompanying risk, thinking is the idea of choice; good citizens choose appropriate actions to manage well-known risks. Yet clients frequently have few resources to address risks and may appear careless and blame worthy as a result.

Underlying risk is fear: of the future, of personal failure, and of the repercussions of that failure. Fear of failure and the accompanying shame often further demoralizes those who already feel inadequate (Stanford, 2010). Workers also realize that they too will be blamed and shamed if they fail to assess risk thoroughly using agency provided tools. In the name of risk, a great many actions that might be questionable are deemed acceptable.

> True fear is a gift. It is a survival signal that sounds only in the presence of danger. Yet unwarranted fear has assumed a power over us that it holds over no other creature on Earth.
> de Becker, 1997

Risks are defined outside the milieu of clients and social workers as they sit down to begin work together. Instead, they have been named by others in positions of considerably more power. The cornerstone of practice, how clients define their needs, is not recognized in this discourse. Working from a risk avoidance stance, social workers often fail to recognize the risks they are asking their clients to take. Leaving a spouse or neighborhood can seem like enormous risks calling upon a great deal of fortitude to those undertaking such drastic changes but are rarely seen in that light.

Social work is founded upon a commitment to growth and change. Yet, risk calculations are often made on the basis that the past determines the future, a contradiction that can prove difficult to resolve. Overall, the possibility that risk is used to transform economic and social changes into individual problems is a process that social work must explore and resist.

In a study of social workers involved in risk assessment in child welfare, these contradictions were rarely identified (Swift and Callahan, 2009). The prospect of preventing harm to children in the messy, busy work of child protection encouraged social workers to accept risk as an uncontested concept supposedly buttressed by science. Further, most of the research on risk in social work has taken place in first world countries, primarily Europe, Canada, the United States, and Australia and remains largely accepting of current conceptions of risk and its

importance for improving practice. The small body of research that has raised critical questions about the possible impact of risk practices on increasing inequality and on blurring the importance of culture and environment is frequently unheralded. Thus notions of the importance of risk assessment instruments and risk management approaches in improving social work practice drift over to other countries where social work is an emerging profession. They may be adopted unchallenged as evidence that the social work profession is gaining ground.

This discussion of risk and its implications for social work is told as a cautionary tale. Nonetheless, it is undeniable that many social workers work in present day organizations where assessing risk and responding to these assessments is a requirement of their practice. And their clients do face risks that, if left unattended, may cause harm. Thus, all of these contradictions inherent in risk thinking may seem tolerable for social workers if assessing and managing risk proved effective in reducing incidence of harm.

Risk Assessment

> Risk assessment is inherently subjective and represents a blending of science and judgment with important psychological, social, cultural, and political factors …. Whoever controls the definition of risk controls the rational solution to the problem at hand. If risk is defined one way, then one option will rise to the top as the most cost-effective or the safest or the best. If it is defined another way, perhaps incorporating qualitative characteristics and other contextual factors, one will likely get a different ordering of action solutions. Defining risk is thus an exercise in power.

Translating risk into risk assessment instruments designed to measure risk levels and thus triaging often scarce resources is a logical step and indeed these instruments have proliferated in social work, as well as other professions. A review of the literature across health and human service professions indicates that risk assessment has flourished in teaching, policing, nursing, medicine, criminology, gerontology, psychology, and psychiatry as well as social work, although studies that compare these developments across more than one profession are rare (some exceptions are Swift and Callahan, 2009; Hannah-Moffat and Maaurutto, 2003; Parsloe, 1999). Indeed, risk assessment is considered a means by which professionals coming from different orientations and organizations can work together to standardize their assessments of complex situations and 'sing from the same hymnbook.' The field of violence against women and children is a clear example where common risk assessments across professions are encouraged (Family Violence, Risk Assessment and Risk Management, 2007).

Examining the risk assessments of various professions reveals that these instruments have a great deal in common. Risk factors are identified from research and practice with a scale for judging the levels of risk accompanying each factor. Criteria for assigning a numerical score for each risk factor are also provided along with opportunities for those completing the assessment to offer comments and compute an overall score. Some of the instruments developed more recently provide a list of mitigating factors or strengths, again to be scored. Overall risk assessments appear like something of a checklist with factors and categories of factors, scores, and identified tasks for professionals to complete the assessment.

However, some significant differences exist. The requirement to complete a risk assessment for each client varies among professions and their particular field of practice. Not surprisingly, in those fields where the central task of professionals is to determine individual risks to others and the community, risk assessments appear as mandatory features of practice with more rigorous procedures attached to them. In social work, risk assessments have taken a central place in practice in corrections, community care, and child welfare (Barry, 2007). Over time, risk assessments that began as voluntary procedures may become mandatory as they become incorporated into the overall risk management strategy of an organization. In situations where risk assessments are mandatory, the process of completing these are often embedded in a computer-guided work process, where each step is required for the completion of the next and where failure to follow procedures can result in sanctions.

Most risk assessments focus upon individual characteristics, experiences, and behavior. For instance, a typical risk assessment in child welfare includes characteristics of the caregiver such as age, gender, past experiences of abuse as a child, history of mental health problems, substance use, behavior of partner in the home, and so forth. Some of these characteristics are unchangeable: age, gender, and past experiences, for instance, and some can be the focus of potential work.

Less frequently risk assessment includes environmental, economic, and social factors as these factors are seen as beyond the mandate of personal social services to address. But there are exceptions. Public health and social welfare researchers may examine the incidence of a particular phenomenon among a large population and make public policy recommendations. For instance, the PRAMS program in the United States explored the diminishing reduction in infant mortality using large population databases and identified those factors leading to increased risks of death for infants with accompanying program and policy solutions: a social risk assessment rather than an individual one. In the field of community care, environmental risk assessments may occur, such as safety audits of seniors' facilities to mitigate the occurrence of falls.

The degree to which clients participate in risk assessments also varies. For some, particularly those that are voluntary, participation may be an intrinsic part of the engagement with clients, helping them to assess and manage their own risks. However, many times clients are unaware of risk assessments. Data may be taken from their file and worker observations without their knowing, particularly if their behavior is seen to be a potential risk to others. The degree of professional preparation and training for those administering risk assessments also varies. Some worry that the prescriptive nature of risk assessment work endangers professional autonomy and may lead to the replacement of professionals with less prepared workers.

The construction of risk assessments across disciplines has taken two courses. One path, based upon actuarial thinking, uses rigorous research procedures to determine causal links between individuals, situations, and behavior. Another model,

termed consensual, focuses largely upon theories and professional practice wisdom to identify risk factors. It remains challenging to develop actuarial models in social work, although many attempts exist. The most egregious behaviors to be predicted and prevented such as suicide, serious injury, and homicide occur rarely and thus the sample size is small and includes a myriad of intervening variables (Powell et al., 2000; Caldwell, 2002; Munro and Rumgay, 2000). However actuarial models are demonstrated to be more accurate than consensual ones and there is an ongoing search to develop and refine new ones (Gambrill and Shlonsky, 2000; Baird and Wagner, 2000).

Risk assessments in social work are usually a combination of actuarial and consensual models with an emphasis on professional theories and practice wisdom (Shlonsky and Wagner, 2005). For instance, an analysis of risk assessments commonly used in child welfare in Canada and the United States indicates that three particular theories guide the selection of variables: cycle of violence, child developmental stages, and attachment theories (Swift and Callahan, 2009). While all of these theories and the research supporting them are important to social work they have nonetheless faced critical analysis for many reasons including concerns about their ethnocentric foundations.

More problematic is the accuracy of these instruments in predicting future harm to children or other individuals. Exhaustive reviews of the literature on risk assessment in various fields of practice in social work have led to very cautionary conclusions about their capacity to forecast danger (Rycus and Hughes, 2003; Barry, 2007). One recent review covering international research and literature on risk assessment in corrections, community care, and child welfare concludes:

> There is little confidence in the predictability of risk assessment tools and yet they are becoming the priority and the focus of much worker-client contact; tools thus tend to replace rather than inform professional judgement; … the relationship between worker and client is paramount to effective working and yet is being eroded by the language and politics of risk.

> Barry, 2007: 8

The Social Work of Risk Assessment

Social work has always been problem focussed, whereby problems bring or compel people to seek help from social workers. From its inception, social workers have focussed upon individual and social assessments as a central task in analyzing problems and commencing strategies to work with their clients. Mary Richmond, the acknowledged pioneer of social work, framed assessments as "the attempt to arrive at as exact a definition of the social situation and personality of a given client" (p. 50) through the gathering of real, testimonial, and circumstantial evidence.

Risk assessment continues this history of making assessment on the basis of evidence but with one distinctive difference: previously identified and specifically named risks of future calamities have largely replaced an assessment of the client's present problems. These risks have been arrived at outside the realm of the social worker and individual client yet significantly shape their work together. The client's definition of the problem is not a focus of the assessment and in fact clients learn to be careful in identifying their problems lest it cause their risk scores to rise. Also they must take care challenging the selected risks on the risk assessment as to do so might appear that they were questioning science and not just the worker. Contesting their scores is also difficult as they may not have access to the information upon which the judgment was made. It is a test given by an expert which they pass or fail.

One of the major gaps in the literature and research on risk assessment is the actual work involved in completing such assessments (some exceptions are Parada, 2004; Broadhurst et al., 2010; Swift and Callahan, 2009; Munro, 2010). An intensive study of this process in child welfare where risk assessments have been mandatory features of practice and heavily governed by procedures reveals that although assessing risk is the expressed aim, social workers struggled to believe in this goal in the face of challenges such as the increased time required to gather and record information, the immediate needs of the clients, the limited resources of the agency, and the rigidity of the risk assessment instrument in conveying clients situations. Although the instrument appeared as scientifically based and objective, social workers were fully aware of the subjective nature of information gathering and the assigning of scores. In particular, social workers grappled with the problems of seeing their clients in terms of the risks they present and not their strengths. Some found ways to skirt the standardized system of assessment and bring individual needs and their own assessment to the situation at hand. Managing their own cognitive dissonance was a daily feature of the work.

It is also true that social workers place value on risk assessments for a variety of reasons. Working in highly volatile and dangerous situations where their professional expertise may be ignored by others, social workers can use the power of risk assessments to gain creditability for their opinions from other professionals as well as recalcitrant clients. They can use them as an 'aide memoire' covering areas in their assessments that they may not have considered without the risk assessment at hand. Even if calamities occur, as they will, social workers can protect themselves from blame by following all risk assessment protocols (Munro, 2004).

However in the face of these significant problems with risk assessment, changes have occurred. Researchers have intensified attempts to nail down risk factors supported by quantitative methods. Risk assessments themselves have been modified to include strengths as well as risks, family assessments and immediate safety assessments. These latter developments beg the question whether 'pure' risk assessments designed to anticipate future events are fading from view and are being replaced gradually by Richmond's original vision, gaining 'a picture of the social situation and personality of the client.'

Risk Management

While a great deal of research and practice has focused upon perfecting risk assessments, very little attention has been paid to addressing risks, once identified (some exceptions are Brown, 2004; Swift and Callahan, 2009; Munro, 2010). Overall the essential value dilemma in risk management is illustrated in public debate between the Canadian Paediatric Association

and their American counterparts regarding increased screening for autism. The Canadian association members argued that it was unethical to spend more resources screening for autism when in fact treatment was uncertain and unavailable for most children already diagnosed. Further, they argued, resources would continue to be directed to assessment from treatment, an imbalance that already existed.

An in-depth study of risk management in child welfare revealed how this dilemma plays out in practice (Swift and Callahan, 2009). Social workers charged with risk reduction must address the risks identified on the assessment with the same tools they have always had at their disposal: closing the case before service, offering programs for parents and children, removing parents from the home, and/or removing children. The time-consuming process of risk assessment continued to limit the resources available for any of these options except case closure and child removal, a legislated response. Not surprisingly the selection of these two options rose markedly in Canada during the time when risk assessment was the guiding policy in child welfare.

However, upon further examination, it was also apparent that an increasing percentage of parents were 'repeaters,' those whose cases were closed after they had received service to lower their risk scores, only to be reported again. The risk assessment and management processes produced this circle. Factors on the risk assessment based upon past events score highly, for instance parents raised in foster care or parents about whom previous complaints had been made. The programs they were required to take were not necessarily related to the risks that had been identified but were simply programs usually available in child welfare. As there were limited spaces in these programs, staff members whose agencies depended upon government contracts were encouraged to demonstrate risk reduction and social workers similarly were pressured to move the case along. Hence, parents were discharged, only to be reported again. Risk scores were higher the next time and so the cycle was repeated.

Not surprisingly, parents were never sure where they were in the process but felt governed nonetheless by the specter of the social worker appearing again. They were often right.

Given the confluence of factors: the heightened attention of risk to individuals and others, the uncertainty of risk assessment instruments, the modest resources available for risk reduction and the public demand for political, organizational, and professional accountability when things go wrong, taking the safest risk management approach often appears to be the best course. This is true for child welfare, corrections, and community care, where the safest course in all these fields may be institutionalization. It is however the most expensive. This fact alone may be most significant in rethinking risk assessment.

The Future of Risk

This article began with the question about whether risk assessment has lived up to its original promise: to help social workers predict future tragedies and prevent problems and at the same time to justify intrusion into the lives of individuals on the basis of prevention. The evidence from several different jurisdictions and fields of practice indicates otherwise, at least as risk assessments are applied to individuals. Instead they have increasingly consumed resources while taking away from efforts to deal with present problems. Clients have been significantly disenfranchised in the process, sometimes having little input into their risk assessments and certainly minimal power to contest their scores. At the same time social workers are expected to reduce risks with no additional resources or technologies and face risks themselves if they fail to do so. The contradictions, always apparent in work with unwilling clients, have been exacerbated and the tried and true staples of social work: relationship and client involvement are more difficult to incorporate into practice.

The capacity of financial prediction formulas to adequately predict and respond to risk was found greatly wanting during the economic meltdown of 2008 and current promises are more modest. A recent advertisement for a prominent investment company states:

> No one can fully predict tomorrow's risks. But in today's fundamentally changed investment world, the risks are less foreseeable and more misunderstood than ever…
>
> *The New Yorker*, 3 December 2012, 53

Rather than accept assumptions that increasingly sophisticated risk assessments applied to individuals can prevent tragedies from happening, social work would be wise to reframe the message, as indeed financial institutions have done. Social workers and their clients also work in a world fraught with hazards, where resources have diminished and inequalities have been exacerbated. Predicting individual catastrophes is a far more complex task than forecasting financial disasters. Parton (1998) has long urged the need for rehabilitating concepts of ambiguity and uncertainty in social work.

While social workers may be less capable of predicting what one individual might do in the future, they have solid evidence that conditions such as poverty, poor health, limited education and opportunities, stigma and homelessness increase the likelihood that 'bad things' will happen to individuals overall. Social risk assessments can continue to illuminate these messages.

Social risk remains a useful term to mobilize responses for particular groups of individuals. Programs for such groups as those at risk of contracting diseases or dropping out of school, or giving birth to underweight babies, are easier to mount with evidence of social risk as a central rationale. There are limitations. Social risks do not necessarily translate across boundaries both in substance and the priority that any one culture will give them.

But what about individual risk assessments? The experience over the past several decades leads to clear cautions. Those instruments most reliable and valid are those with the fewest risk factors and contain items that social workers know already to be associated with possible misfortunes. Moreover, the question whether responses and resources are available to deal with risk, once uncovered, is crucial. The portability of individual risk assessments across geographical boundaries is highly questionable without intense scrutiny of the different economic, social, and historical contexts which frame them.

At the core of these cautions is the fundamental concern that the frail science of prediction is used to paper over ideological agendas that work against individual well-being, professional practice, and social justice.

It might be helpful to look beyond risk assessments at other paradigms that address clients whose destructive behavior affects themselves and others and who resist the intervention of social workers. One option is harm reduction, an approach that has gained a great deal of traction in the field of addictions, not without controversy. It refocuses the gaze from risk in the future to harm in the present. Harm includes damage to individuals as well as to their family and the community at large. The aim of intervention is to help individuals stabilize their situation by reducing their destructive behaviors. Interventions include learning about safer injection practices and general health care, offering free substances and medications, and a wide range of supports, including peer helping. It does not begin with the goal of abstinence but indeed abstinence may occur at some point. It is not necessarily time limited as stabilization of individuals may require ongoing support, although over time those being helped may become involved in harm reduction work on behalf of others. One of the major challenges of harm reduction is using strategies to reduce the stigma attached to those who misuse drugs and alcohol. All of these actions reduce costs to families and communities. Adapting harm reduction thinking to corrections, child welfare, and community care could address many of the shortcomings of risk assessment.

We began this article with the aim of examining the promise of risk assessment after two decades of ongoing research and practice. Social work took risk assessment on board energetically and without much scrutiny because it seemed to address intractable contradictions concerning helping and threatening, treating and preventing. There is a lesson to be learned from this experience concerning the necessity of critical analysis. As Theodore Parker (1810–60) once said: "Magnificent promises are always to be suspected."

Risk Screening, Testing, and Diagnosis: Ethical Aspects

Göran Hermerén, Lund University, Lund, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

After an initial clarification of the notion of the risk, a brief discussion of the distinction between testing and screening, and of the difficulties of defining 'genetic information' in a precise way follows an overview of public concerns raised by genetic testing and screening. Next section reviews various types of ethical issues in this context. The challenges are not the same for all types and purposes of such methods. The following sections therefore discuss issues raised by preimplantation diagnosis, prenatal diagnosis, prenatal and neonatal screening, presymptomatic testing, testing at the workplace and forensic uses of genetic tests. Finally some future concerns are outlined briefly.

The Human Genome Organization project has increased enormously the possibilities to predict disability or disease either for an individual or for his or her offspring. Information obtained from genetic testing raises ethical and legal issues that have been debated for several decades. New issues are emerging due to rapid advances in molecular genetics.

From an ethical point of view, risk screening, genetic testing, and diagnosis belong to the most controversial and contested areas in contemporary medicine. The new genetics will have a profound impact on our self-images and on our understanding of the relations between environment and heritage. Conceptual, normative, and empirical issues are here intertwined in a complex way. To begin with, a preliminary clarification of the key concepts will be necessary.

The expression 'risk' will here be taken to refer to an adverse or negative future event that is probable but not certain, for example, given a certain exposure. Any risk can then be analyzed in two components: the probability of occurrence of an event and the magnitude of its negativity (including kind, degree, duration, and timing) according to certain more or less explicitly stated norms and values. Risk assessment accordingly analyzes these two components, while risk management proposes strategies for handling the risk in ways that minimize the negativity and probability.

However, risks involving probabilities are not the only the sort of risks that are relevant in this context. The expression 'epistemic risk' has been coined to refer to risks due to ignorance, and in particular due to ignorance of what we are ignorant about (e.g., Sahlin and Persson, 1994). This notion is particularly relevant to many clinical applications of molecular genetics, involving unknown factors. The ways in which these risks are communicated will then be important from an ethical point of view.

Testing should be distinguished from screening.

Harper has proposed the following definition: "Genetic testing is the analysis of a specific gene, its product or function, or other DNA and chromosome analysis, to detect or exclude an alteration likely to be associated with a genetic disorder" (Harper and Clarke, 1997). Testing refers to procedures performed at the request of individuals or families, and should always be voluntary. This holds also for genetic testing of members of families known to be at high risk, such as the siblings of persons with cystic fibrosis (Wertz and Fletcher, 1989).

'Screening,' however, implies application to large population groups, to entire populations or subsets of populations (e.g., pregnant women, newborns, or job applicants). Screening is not performed at the request of individuals or families but rather based on policy or public health decisions. It may be mandatory or voluntary.

Both the expressions 'genetic information' and 'genetic disorder' are vague and ambiguous concepts (Zimmern, 1999). The same holds for the key concepts of health, disease, and illness. The advances in molecular and clinical genetics may profoundly change our understanding of the latter concepts. They may have an impact on health care policy, on the patient–physician relationship as well as the way in which access to care is allocated (Murray et al., 1996).

Genetic information differs from other private information in that it reveals information not only about a particular individual but also about that individual's blood relatives. Genetic test results may also provide information about population groups. Moreover, genetic information can be obtained from any cell in a person's body, not just by examining, for example, particular malfunctioning organs or tissues.

The concept of genetic information is difficult to define and delimit in a clear and uncontroversial way. Just by asking for the age of a person's parents and grandparents, genetic information in a certain sense can be obtained. The necessary and sufficient conditions for a disease or disorder to be 'genetic' or 'hereditary' are far from clear. If the expressions 'genetic information' and 'genetic disorder' are to appear in legislative texts, they have to be made precise.

There are many kinds of genetic disorders, including (1) chromosome changes, like trisomy 21 or Down's syndrome, (2) monogenetic disorders which depend on a mutation in one gene, like Huntington's chorea, and (3) polygenetic disorders like diabetes which are due to mutations in several genes in combination with environmental factors. They are complex and multifactorial.

These distinctions are important for several reasons. What holds for monogenetic diseases concerning genetic determinism cannot be generalized to genetic disorders of other kinds. Thus, presymptomatic testing can be done for disorders in group (2) but rarely and with much less certainty, if at all, for those in group (3).

Public Concerns

Genetic testing may be beneficial in those cases where early detection makes a difference, for example, makes it possible to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31032-7

prevent or cure the disease. The validity and the reliability of the test methods will then be of crucial importance. The background of many national screening programs, like the one launched in Ontario, Canada, in 1999, to detect risk of hereditary breast, ovarian, and colon cancers is that early detection can lead to medical interventions and surveillance. This can significantly reduce the risk of developing the disease and hence be cost-effective.

The concern expressed over genetic testing and screening, however, is that it may threaten privacy and civil rights and be the basis of genetic discrimination or stigmatization of individuals as well as of groups. Moreover, it has been feared that widespread use of genetic testing will help to foster intolerance of people with genetic variations. It may be difficult, too, if not impossible, for people with certain inherited disorders to obtain a life insurance. Finally, people may feel a pressure to be tested, as a result of cost–benefit analysis. In general, of course, the negative consequences of testing people and disclosing information about their test results to blood relatives will have to be weighed against the benefits of this, if any, for those concerned. However, this weighing operation is far from simple.

Direct-to-consumer testing (DTC) has emerged as an increasingly controversial issue. Under what conditions can it be justified? What could and should be done about different forms of DTC? Consumer protection is obviously a relevant concern. But internet sales are difficult to regulate. Hogarth et al., 2008 provide an overview of the current landscape for the developing market for DTC genetic testing, and reviews the legal, ethical, and policy issues raised by this testing.

The need to be cautious when considering and interpreting such testing has been stressed (Dandara et al., 2013). The reason is that the clinical validity and utility of genetic tests for many complex multifactorial disorders is questionable. Recommendations to protect consumers and healthcare providers are proposed by these authors. Patrinos et al. (2013) discuss a variant of the DTC business model, where private molecular genetic testing services are offered for sale over the counter by pharmacies, and the authors stress the lack of awareness on the part of both the patients and the general public with respect to the potential benefits and risks of the tests offered.

Guidelines for genetic testing and screening have been proposed in the attempt to maximize the beneficial consequences and minimize the adverse ones (by e.g., the Nuffield Council on Bioethics (1993); the Danish Council of Ethics (1993); UNESCO (1997); the Council of Europe (1996, 2008)). These guidelines include recommendations concerning genetic counseling, informed consent, disclosure to individuals and family members, confidentiality, employment, insurance, as well as public policy. The commercial availability of genetic test kits raises both operational and ethical issues, dealt within the principles and recommendations suggested by National Institutes of Health (1997). This report discusses the validity of genetic testing, deals with genetic counseling and the informed consent process, as well as recommendations on quality assurance measures for laboratories performing genetic tests and the need for a national body with the authority to review genetic testing procedures.

The future development, indicated by the increased transition from chance to choice (Buchanan et al., 2000), includes a growing multitude of choices, possibilities to test earlier, and without procedure-related risks. This raises many ethical issues, not only about who will get access to the new technologies.

Ethical Issues

The ethical issues include the risk for potential harm by false positives and false negative, and by invasive procedures, the risks for genetic discrimination, how to promote and protect important values like autonomy (respect for persons), privacy, confidentiality, justice and fair access, and more generally how to estimate, weight and balance benefits and harms. There has to be a reasonable proportion between risks and benefits, but how this is to be understood more precisely is not clear (Hermerén, 2012).

Harms and Benefits

Invasive procedures can be harmful, e.g., by causing miscarriage. But harm can also be created in other ways. The accuracy of the tests – their validity and reliability – and the predictive value of the test or the screening method is clearly an important issue in this context. To estimate the predictive value, one has to be able to compute the number of false positives (who are worried unnecessarily) and false negatives (who are lulled into false security) as well as to know about the prevalence of the genetic disorder.

Autonomy

It has often been recommended that genetic information in health care should be acquired and used "in a manner that respects the autonomy of individuals" (Institute of Medicine, 1994), but it has proved hard to explain the precise meaning of this in a noncontroversial way. The autonomy of what individuals should be respected? Sometimes respecting the autonomy of one individual may conflict with respecting the autonomy of another. The principle of reproductive autonomy is problematic in the context of prenatal testing, because of possible interference with the supposed rights of the unborn child (Haker, 2008).

Traditional ways to promote and protect autonomy include nondirective counseling and informed consent. A general problem raised by all forms of genetic testing and screening is, first, how to give nondirective information, that is, information that makes autonomous decisions possible by individuals and couples, and then to obtain consent in a way that avoids exercise of pressure.

Why is nondirectiveness an important goal? In brief, the reasons are the value of autonomy and the importance for geneticists to dissociate themselves from the dark history of genetics, from abuse of genetics for eugenic purposes. But nondirectiveness in practice is not uncomplicated, and the goal is also controversial. Hardly surprising, there is an ongoing debate on the process of genetic counseling beyond nondirectiveness (Clarke, 1994; Harper and Clarke, 1997).

Particular problems are raised by the testing of individuals or groups with reduced autonomy, like children, demented people, or immigrants who do not understand the language.

The testing of a healthy child could arise in at least three different contexts (Chadwick, 1998): predictive testing, to see if the child will develop a specific disease that runs in the family; carrier testing, to see if the child may be at risk of having an affected child; and a screening test unrelated to family history to identify children with increased susceptibility to some common disease such as diabetes or ischemic heart disease. Children are vulnerable and their parents therefore have to be involved in the decision procedure.

But how? The nature of parental consent and the degree to which children are to be involved according to their maturity need close examination. If relatives are to be informed, who should do this? The geneticist, the hospital, or those already tested? And in what way? How many relatives should be informed? How closely related to the person asking to be tested (the index person) should the relatives be for the clinical geneticist to be responsible for informing them?

Different consent models are available, each with their own pros and cons. One main alternative is called 'opt in,' which means that if you have not said yes, you have said no; another is called 'opt out,' which means that if you have not said no, you have said yes. The conditions under which any of these models may or must be used is an important ethical issue.

Informed consent has traditionally been one of the basic principles in practical medical ethics. But the ambiguity of the term 'informed consent' has been stressed by Manson and O'Neill 2007. Moreover, new developments in genetic testing challenge this principle in its traditional form. It has, for instance, been suggested that opportunistic screening presents the most serious challenge to patient autonomy in this century, particularly in prostate-specific antigen screening, newborn screening and prenatal diagnosis of maternal blood tests for fetal anomalies (Davis, 2013).

Recent developments in genomics technologies have paved the way for broad genome-wide testing for dozens of diseases at the same time. Bunnik et al. (2013a) have proposed a tiered-layered-staged model for informed consent in personal genome testing. It is suggested that this model for informed consent can help to overcome the ethical problems of information provision and informed consent in direct to consumer personal genome testing.

Whole-genome sequencing and microarray based analyses also challenge the feasibility of providing adequate pretest information and achieving autonomous decision making. It has been argued that informed consent is a prerequisite but requires a new approach (Bunnik et al., 2013b). Preliminary and general directions for the testing offer and for the informed consent process are presented in their paper.

Privacy and The Right to Know

The challenge to genetic privacy concerns the control of personal genetic information. Privacy has two dimensions, according to the Canadian Human Rights Commission (1992): protection from the intrusion of others and protection from one's own secrets. Does this entail a right to genetic ignorance, a right not to know about one's own or one's relatives' genetic risk profile? Is there a duty for geneticists or tested persons to disclose such information to those who might benefit from it?

If so, what is the basis of such rights and duties, and what are the consequences for the various people concerned of accepting or rejecting them? Opposite positions have been argued for by Rhodes (1998) and Takala and Hayry (2000). Several compromise positions have been put forward. Tested persons should be encouraged to share what they know about their genetic risk profile with their blood relatives, when this information would be of vital health interest to their relatives (Chadwick et al., 1997; Hermerén, 2000).

The right to know your genetic parents has been a lively discussed issue in recent years. A central role in the debate has been the comparison between different situations. Some have argued that the right to know the identity of the gamete donor should be extended to naturally conceived children with misattributed paternity. Routine paternity testing at birth should therefore be carried out (Ravelingien and Pennings, 2013). Others have questioned the similarities between gamete donation and misattributed paternity and argued that they should be treated differently. Underlying this debate is the contested value of genetic relatedness, on which there are many different views.

Confidentiality of Genetic Information

The confidentiality of the information needs to be protected against third party interests, including other family members, employers, and insurers. It has been suggested that genetic information should not be given to unrelated third parties, without the explicit and informed consent of the tested persons. In many countries, access to genetic information is regulated by law. The conditions or criteria under which medical confidentiality may or must be breached are bound to be controversial (Harper and Clarke, 1997).

The practical problems raised by genetic testing also have to do with how to estimate and evaluate risks, communicate them in an understandable way, and decide which risks are acceptable and which are not. This includes the risk that a person will have an increased risk for a genetic disorder and the risk that the test result is not accurate. Communicating risks is obviously an important part of the genetic counseling process.

Justice and Fair Access

Finally, there are issues of justice and fair access. The health care systems in most countries are under increasing economic pressure. Different ways of cutting costs, manage the care, and require copayment by patients have been introduced. If testing and screening is to be done on an equitable basis, it should not be available on the basis of such accidents as in which geographical region a person happens to be born.

The ethical problems outlined above arise in somewhat different ways, according to the type and purpose of testing or screening. The challenges are not the same in all cases. In particular, certain forms of screening and presymptomatic testing for late onset genetic disorders present problems from an ethical point of view. Some of the most common types of genetic testing and screening will therefore be described below along with a brief indication of the particular ethical problems they raise.

Types of Testing and Screening

Taking the chronological development of a person's life as a point of departure, rather than the historical development of the various technologies, we may distinguish between methods used before implantation of the fertilized egg in uterus (preimplantation), before the individual is born (prenatal), when the individual is newborn (neonatal), after birth but before symptoms are visible (presymptomatic) or later to find out if the person or his or her future children are at risk to develop some hereditary disease (carrier). In addition to them, there are genetic tests and screening methods for specific applications, for instance, in workplaces (susceptibility) or in potentially legal cases (forensic).

Preimplantation Diagnosis

Preimplantation diagnosis means that the diagnosis is carried out before (in connection with *in vitro fertilization*) the pre-embryo is implanted in the woman's uterus. If there were a history of sex-linked diseases in a family, it would then be possible to prevent a child with such a disease being born. Thus the resulting pregnancy could be normal and the woman would not have to abort the fetus at a later stage or give birth to a child with a very serious or lethal disease. Preimplantation diagnosis is becoming an established medical practice in many countries.

The first serious ethical problem that arises is to whom these tests should be offered. Usually, they are limited to severe illnesses and to persons in specific 'high risk' groups. But both these criteria are value laden, and the indications may be narrowed down or widened. There are also considerable variations not only between lay people but also between geneticists over the severity of different genetic conditions (Chadwick, 1998).

Preimplantation diagnosis at the beginning of the twenty-first century is thus limited to sorting out fertilized eggs carrying genes associated with severe diseases for which there is no cure at present, like Huntington's chorea and certain X-linked diseases. Concern has been expressed that the practice may be extended to diseases that are less serious (Shenfield, 1997). Obviously, there is a risk of a slippery slope in this area.

Preimplantation diagnosis also, at least theoretically, opens up possibilities for a shift of power from the woman to the geneticist, as well as for cloning and manipulation of human pre-embryos that many people find too risky or simply ethically unacceptable. In many countries, manipulation of human pre-embryos is illegal.

The technological development in this area is rapid. For instance, Harper and Harton 2010 describe the current use of array technology and make suggestions for future use of arrays in preimplantation genetic diagnosis (PGD) and preimplantation genetic screening (PGS). They also discuss the steps that need to be taken if array-based testing is going to prove useful.

Comprehensive techniques like microarray technology and whole genome sequencing have the potential to change the practice of PGD and PGS. Hens et al., 2013 describe an expert panel study of how to deal with the extra information these procedures yield, including which conditions to test for and who should have a final say on which embryo to select.

Prenatal Diagnosis

Prenatal diagnosis can be regarded as a special case of presymptomatic testing. By prenatal diagnosis it is possible to discern whether a fetus is at risk for various disabilities or diseases.

There are several methods for prenatal diagnosis. Some are visual – either noninvasive, like ultrasonography, or invasive, like embryoscopy or fetoscopy, which uses a camera on a needle inserted in the uterus to view the fetus. Other methods are based on the analysis of fetal tissues (like amniocentesis or chorionic villus sampling). By ultrasound tomography it is possible to create fetal images on a screen.

The distinction between invasive and noninvasive methods is important. The former can do harm during the test procedure, e.g. by causing miscarriage. From that point of view various noninvasive techniques have emerged as very promising, provided that the problem of avoiding false positive and false negative test results can be dealt with adequately. The analysis of fetal DNA in the blood of the mother is one such method that has been gaining ground in recent years.

There are several overviews and discussions of current applications of circulating fetal nucleic acids (cell-free fetal DNA) in genetic testing for different kinds of hereditary diseases, particularly in diagnosis of monogenic disorders (Ma et al., 2013). Genetic skin diseases are of varying severity and this raises issues of the responsibility of doctors and parents in the prenatal genetic testing. The complexity of the issues calls for guidelines about the best practice in this kind of testing.

Allyse et al., 2013 have proposed an ethical framework for clinicians and companies providing noninvasive prenatal testing using cell-free fetal DNA or whole fetal cells as a basis for a set of best practices for the provision of noninvasive prenatal genetic testing. The recommendations include the amendment of current informed consent procedures. The authors strongly recommend that these tests should only be available through licensed medical providers and not directly to consumers.

The indications of when prenatal diagnosis should be offered include advanced maternal age, a genetic history of abnormalities in the family, repeated miscarriages, or previous infants with birth defects. Then a prenatal diagnosis may be offered to provide information to couples about what they can expect. A normal result is found in most cases. If not, prenatal diagnosis may make it possible for them to adjust and may also influence the way in which the baby is delivered.

There has been great concern about the risk of spontaneous abortion induced by the use of invasive methods like amniocentesis or chorionic villus sampling. This is a problem one does not have with ultrasonography and other noninvasive methods. On the other hand, ultrasonography may give information that is unexpected or not wanted, for example, that some organs or limbs are malformed. With other methods, too, one may make unexpected or unwanted discoveries, for example, that the social father is not the biological father.

A well-known issue that continues to be controversial is how to deal with incidental findings in genetic testing. The new genetic technologies have made this challenge even more urgent. Incidental findings can range from identifying

increased risk for certain inherited diseases to revealing misattributed paternity. Should the tested person always be told? If not, what criteria could and should be used to single out the exceptions?

Should incidental findings discovered with whole-genome sequencing or testing be sought and reported to ordering clinicians and to patients or their surrogates? Contradictory answers to this question have been argued for in a discussion of a statement by the American College of Medical Genetics and Genomics (Green et al., 2013; Friedman Ross, 2013).

McGuire et al., 2013 also discuss the recommendations of the American College of Medical Genetics and Genomics to seek and report pathogenic mutations for a short list of carefully chosen genes and conditions. The authors focus on the ethical framework for these recommendations. They argue that standards are needed, that patient autonomy – including the right not to know – should be respected, and that children and adults should be treated equally.

All this serves to underline the necessity of careful counseling before the diagnosis, so that the woman or the couple knows what the test may show and how certain the result is. Informed consent is crucial, but the difficulties of nondirective counseling should not be underestimated.

Other ethical issues raised by this type of diagnosis are concerned with how to preserve the confidentiality of the information obtained. Since prenatal diagnostics sometimes leads to abortion, it may be controversial in the eyes of some people for the same reasons that abortion is controversial. The impact of prenatal diagnosis on our views of people with handicap has also been a matter of concern.

Prenatal and Neonatal Screening

Newborn screening involves the analysis of blood or tissue samples taken in early infancy in order to detect inherited diseases where early intervention can minimize or eliminate the risk of later serious health problems or premature death. In prenatal screening, conventional karyotyping is being replaced by genome-wide array-based techniques (A de Jong et al., 2011).

In screening, a group of individuals is examined directly with DNA, RNA, or biochemical analysis to find those who will later in life have an increased risk of developing a particular genetic disorder. A good screening method is reliable and valid, with a minimum of false positives and false negatives.

A well-known example of uncontroversial neonatal screening is screening for phenylketonuria (PKU), a genetic disease. The reason is that PKU, if undetected, can lead to serious mental retardation. Moreover, it can be discovered easily and prevented through early intervention. For many other conditions, such as cystic fibrosis and galactosemia, the benefits of early detection are more controversial. Screening programs for newborns also raise the issues of freedom of choice and informed consent by parents (Hermerén, 1999).

Newborn screening raises several ethical issues, among them the nature of informed parental consent and how it is obtained, confidentiality and privacy, and the interests of third parties, as well as issues of justice such as equal access to testing and treatment. Moreover, it is clear that more research needs to be carried out on the psychological responses to newborn screening, particularly when the health benefits are disputed (Harper and Clarke, 1997).

Recent technological developments have made it possible to collect a huge amount of information about the genetic status of the fetus. However, this information is to some extent uncertain, its meaning is variable, and its relevance to the woman or the couple contested. It has been suggested that the ethical debate should focus on the clinical context and on the ends of prenatal screening and diagnostics (Schmitz, 2013). If that is done, the ethical debate would be able to provide a more comprehensive and useful analysis of the ethical challenges presented by in particular the new technologies.

People with certain genetic disorders have had difficulties in getting a life insurance. In some countries the right of insurance companies to ask for genetic information has been regulated by law. In Norway, it is forbidden. In other countries – The Netherlands and Sweden, for instance – there has been a temporary voluntary moratorium during which the insurance companies will not ask for genetic information, provided that the life insurance asked for will not exceed a certain amount. This is still a very controversial area (Sandberg, 1996).

Presymptomatic Testing

Individuals may be tested for monogenetic disorders (of which there are many though each is fairly rare) by DNA analysis before any symptoms are shown. If an early diagnosis is of value, because the disease can be prevented, presymptomatic testing is fairly uncontroversial. If the disorder cannot be prevented, the value of presymptomatic testing is more difficult to judge. This holds also in cases where there is a method of prevention, but it is nevertheless impossible to guarantee that the person tested positively will not get the disease (e.g., breast cancer).

In addition to the obvious difficulty of informing people in such a way that they can make autonomous decisions, presymptomatic testing raises problems about how the information obtained from the tests should be handled, and who should have access to it. Likewise, it is controversial whether blood relatives should be contacted and who should contact them in that case (the person tested, the hospital, the clinic, the geneticist, etc.). Moreover, in many countries there is great concern about how to prevent certain external third parties, like employers or insurers, from getting access to information about the test result.

Carrier Screening

Carrier screening identifies individuals with a gene or chromosome abnormality that may cause problems either for offspring or for the person screened. The testing of blood or tissue samples can indicate the existence of particular genetic trait changes in chromosomes or changes in DNA that are associated with inherited diseases in asymptomatic individuals. Carrier screening exists for sickle cell anemia, for Tay Sachs disease, as well as for cystic fibrosis, Duchenne muscular dystrophy, hemophilia, and Huntington's chorea.

Carriers have one normal copy of a gene and one copy that varies from the normal gene. Since one gene is normal, the carriers ordinarily do not exhibit symptoms of a genetic

disorder. A woman who is a carrier of an X-linked disease such as Duchenne muscular dystrophy or fragile X syndrome, has a variant gene on one of their two X (sex-determining) chromosomes. Her risk of transmitting the variant gene to each child can be estimated accurately.

The purpose of carrier testing is to inform potential parents of their genetic risk profile so that they can make informed reproductive decisions. National screening programs are usually justified by cost–benefit analysis. The question is then which costs and whose costs are taken into account, and how the benefits are defined and evaluated. The importance of cultural differences as to what constitutes benefits, and how benefits are ranked, should not be underestimated.

The right to autonomous choices is an important issue also in this area. Whether the choices open to people found to carry a disease gene are acceptable or not, may depend on their life plans, their ethical views, the laws of their country, as well as their culture and social customs. Before a carrier screening program is decided on and implemented, these questions need to be considered. In practice there may be subtle coercion, even if a carrier screening program is formally voluntary.

Screening the subset of a population at risk rather than the entire population makes sense from a medical and economic point of view, but selecting target groups for such screening programs also creates ethical problems. For example, there have been in the past controversies over whether some screening programs in effect had a eugenic purpose, particularly when the diseases screened for are overrepresented in certain ethnic groups.

Testing in the Work Place

Susceptibility screening can be used as a form of presymptomatic testing, but is also used to identify workers who may be susceptible to toxic or carcinogenic substances such as benzene in their workplace (Van Damme et al., 1997; Surralles et al., 1997; Jarvholm et al., 1999). This susceptibility may lead to occupational health problems and future severe disabilities.

Van Damme et al. (1995) have proposed a conceptual model of the complex interactions between exposure, acquired and inherited susceptibility, and risk for disease. The validity of tests for determining genotype and phenotype and their relevance for the disease must be evaluated critically to provide an objective basis for ethical discussions. The acceptability of such tests is related to a number of issues which Van Damme et al. identify and discuss.

Genetic testing of employees and job applicants is controversial. The first basic question concerning testing in the work place is simple – for whose sake is the test performed? Is the test performed in order to protect persons with increased (inherited) susceptibility to hazards at the workplace? Or is the test in the interest of the employer, so that the employer can avoid improving the working conditions and avoid hiring people who would be damaged by the work they do? Here it is essential to separate the situation of the job applicant from the situation of the person already with a job. The latter could be monitored for exposures and early effects of, for example, toxic substances on the genes.

There are methods of detecting inherited predisposition to cardiovascular diseases as well as to adverse effects from otherwise well-tolerated exposures related to the job. Clearly, with widespread use of genetic testing in the workplace there is the obvious danger of discrimination and stigmatization of individuals or groups. It may be tempting for employers to use tests to select only workers who will be able to work in the present working conditions, instead of improving the working conditions. The result could be that large groups of people would be barred from the job market.

The discussion of the validity and predictive value of the methods used in genetic testing in the workplace including the ethical and societal issues raised by these methods has continued with many contributions. For instance, MacDonald and Williams-Jones 2002 discuss arguments for genetic testing the workplace, the objections to such testing, and propose pragmatic criteria, which – they argue – if met, "would make it permissible for employers to offer but not to require workplace genetic testing."

Particular attention has been focused on the risks for genetic discrimination (Krumm, 2002). This has been the central issue in the debate. Holtzman discusses the opinion by the European Group on Ethics on genetic testing in the workplace, in particular the implications of false positives and false negatives. Issues of employment in relation to genetic testing and Huntington's disease (HD) have also been discussed against the background of a widely publicized case in Germany where a woman was refused employment as a teacher because of a family history of HD (Harper et al., 2004).

Forensic Testing

A comparatively new use of genetic testing is to examine a possible genetic linkage between, for example, alleged fathers and their children, or between suspects and evidence discovered in criminal investigations, like hair, blood, sperm, saliva, or skin. The idea is to use genetic methods of analysis to clear the innocent and identify the guilty.

However, concern has been expressed that mistakes can be made. Critics argue that it is necessary to improve the quality control of the test laboratories. Another problem is the confidentiality of the DNA profiles obtained from criminal investigations and stored in national police databanks. For how long time will they be stored? In some countries there are explicit limits to how long time they can be kept. Moreover, who will have access to them while they are stored, and for what purpose?

In some countries, for instance Sweden, apparently no complete genetic analysis is carried out, and the samples are not saved. The information collected in criminal contexts is limited to what is required for a profile that is unique enough (with the exception for monozygotic twins and very close relatives). The intention is to minimize the possibility to extract general genetic information from the forensic data bases.

Concluding Remarks

Since genomic technologies are able to detect genetic variations in patients with high accuracy and at reduced cost, these technologies may change the practice of medicine in the future. But genome-wide data raise many challenges concerning how they are to be interpreted and handled.

Genetic testing and screening should be done for 'health purposes.' This is sometimes stated as a necessary condition for genetic testing (Council of Europe, 1996, 2008). Health purposes could include diagnostic and therapeutic purposes as well as medical research and health care planning. Moreover, 'health' can be defined in several ways. It is important to state more precisely what this means.

Careful counseling remains crucial, as already mentioned. The uncertainties and gaps in our knowledge referred to earlier have important implications for the information provided and the choices actually made. This applies both to monogenic and multifactorial inherited conditions. One of the present concerns is that do-it-yourself test kits for genetic disorders may be bought via the Internet or over the counter without any professional counseling to explain what the findings mean, how certain the test is, etc. There is an urgent need to find ways of regulating the economic interest of commercial biotechnological companies in order to minimize the harm of premature use and overuse of genetic testing.

A matter of controversy is the extent to which attempts to individualize risks by pharmacogenomics (personalized medicine) will save money – and if so, how much – for the health care system. This depends on how the costs are estimated. Which costs, and whose costs, are included, and how are they estimated? Clearly it will have far-reaching effects on the education of medical doctors and the training of general practitioners – costs, which are not easy to estimate. Moreover, and perhaps more important, it will also have effects on the health care system, health care insurance, and priority setting in health care (Sahlin and Hermerén, 2011).

Genetics has a somewhat dark history linked to eugenics. Eugenics can be organized by a state or a political party in power. But eugenic purposes can be also achieved by testing or screening methods in combination with social pressure to abort – and be facilitated by new technologies. Fear has sometimes been expressed that advances in molecular biology might speed up *in vitro* eugenics (Sparrow, 2013). Others (Da Fonseca, 2013) have argued that this is far away, due to the practical limitations to the technique of creating human gametes from stem cells.

Abstract

The concept of risk plays a central role in many contemporary policy debates, but social scientists have observed a paradoxical quality to the social treatment of risk in recent decades. On the one hand, there appears to have been a trend toward the taming of risk; understanding of probability and chance has grown, and certain forms of risk exposure (to some illnesses and natural hazards, for example) have declined. But modernist confidence about the prospects for the control of risk has been moderated and to some extent undermined by related developments. As an example, twentieth-century technologies were associated with new forms of risk, including risks to the whole ecosystem. It seemed that the forces of progress could lead to novel hazards as well as to enhanced security. Furthermore, the legal frameworks and intellectual tools developed for the regulation of risk made it possible to elaborate arguments about risk in ever more sophisticated ways, often challenging 'establishment' interpretations of safety, and thus engendering a more vivid appreciation of risk. The ubiquity of contentious claims about risk and safety has even led some scientists to characterize high modern cultures as 'risk societies.'

Risk and chance have long been understood as key elements of the human predicament, but risk awareness besets whole cultures as well as individuals. Social scientists have typically been interested in risk both from the social-psychological stance of particular actors and in terms of cultural responses to collective exposures. At one level, sociologists have discerned a twofold historical trend toward the taming of risk. Risks have been controlled both in the sense that certain forms of societal and individual exposure to hazards have been reduced, and in the sense that risk and probability have themselves become better understood and made more tractable. Nineteenth- and early twentieth-century confidence in progress and control over nature suggested both that risks were diminishing – previously fearsome diseases could be controlled, dangers to food supply countered through scientific farm management, and so on – and that better understanding of risk and chance was possible, so that one's exposure to risk could be managed and reduced. But this modernist confidence about the prospects for the control of risk has been moderated and to some extent undermined by subsequent developments. For one thing, pivotal twentieth-century technologies including the internal combustion engine and nuclear energy were associated with new forms of risk, including (through climate change) risks to the entire world ecosystem. It seemed apparent that the forces of progress could lead to novel hazards as well as to enhanced security. Furthermore, the legal frameworks and intellectual tools developed for the regulation of risk made it possible to elaborate arguments about risk in ever more sophisticated ways, ironically engendering a more vivid appreciation of risk and eroding confidence in calculations of specific risks. Finally, the complexity of social development fostered distinctively social risks, to do with crime and the increasing uncertainty of social life and the fear of surveillance. This discussion will begin by focusing on the regulatory treatment of risk before moving on to consider the broader social experience of risk.

Risk Assessment: Regulators and Risks

One systematic and extensive body of literature on risk grew out of concerns to make policy and to legislate for risk; this literature can be categorized as concerned with 'risk assessment' and with attempts to set risk assessment on an objective footing. Given the ubiquity of risks, the question for regulators was customarily thought of as: 'how safe is safe enough?' Governments and official agencies recognize that, regrettably, train crashes occur, that drivers are daily involved in automobile collisions, that leaks will sometimes happen even from well-managed chemical plants, and that farm chemicals may impact the environment, agricultural workers, or even occasional consumers. Given that no complex system can be guaranteed to be perfectly safe, the leading approach was to ask about the price of additional increments in safety. From within this consequentialist world view, risk is thought of as the mathematical product of the likelihood of a hazard occurring and the costs to which that hazard gives rise. The policy maker's art is then to minimize risk within the budget that society is willing to spend on safety.

In practical terms, this task was always much more difficult than might be supposed, and certainly more intractable than economists routinely implied. In part, difficulties arose because of the inherent problems of trying to harmonize risk data across various fields. It may be possible to compare the costs and risks of various railway signaling systems, but (in the absence of a superministry of risk reduction) transport, industrial, medical, and agricultural risks cannot be brought within the same calculus. Worse still, both the likelihood of the problem and its consequences commonly defy exact specification. While there are good data on the medical and related risks of typical motor accidents on US and European freeways, the probability and the consequences of nuclear power station incidents can only be calculated in hypothetical ways. Similarly, the risks and costs of 'mad-cow disease' (bovine spongiform encephalopathy, or BSE), an unprecedented form of infection that spread through the food chain near the close of the twentieth century, could not be subjected to the risk calculus in the standard way because we still have no agreed way of knowing who has been infected (until postmortem examination) nor how long it may take for symptoms to appear. Further, the only way to obtain quantitative measures of many risks to humans is to extrapolate from indirect observations, such as rodent bioassays, thereby introducing

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85019-9

additional sources of uncertainty into risk assessment. Without good data, all calculations will be 'rough and ready' and even relatively minor changes in key parameters can radically alter the projected figures for risk. Nor is it even clear that there is a single currency into which all sorts of harms can be converted for the purposes of cost–benefit calculations, not least because some harms may be suffered by natural environments, landscapes or more abstract entities such as biodiversity. Thus in the recent, largely (but not exclusively) European, controversy over the possible link between declining bee numbers and the agricultural use of neonicotinoid insecticides, policymakers and analysts who wished to address the issue in terms of risks faced numerous problems. It was uncertain how much of the harm to bee health was attributable to the insecticides. It was unclear what chemicals farmers would turn to if neonicotinoids were withdrawn. And it was impossible to put an agreed figure on key costs: the decline in agricultural productivity that might result from not using the insecticides, the value of the pollination services carried out by the bees that might be protected by banning neonicotinoids, and the worth of the lives of the bees themselves that might be saved.

Despite these persistent difficulties, one line of literature about risk has been devoted to exploring what are thought to be shortcomings in the public's understanding of risk. Lay people appear to make irrational and statistically unsupported assessments of the relative risks of different hazards, and to demand high levels of risk reduction without being aware, or taking due account, of the costs. In the extreme case, the public appears unwilling even to accept the cost–benefit approach, but has no systematic alternative with which to replace it. As an added complication, despite frequent public protestations of anxieties about risk, market mechanisms seem to imply that people are not necessarily very risk averse: in the automobile market, vehicles have tended to sell on aesthetic and performance criteria rather than on safety; and consumers continue to eat fatty foods and to avoid exercise, despite well publicized links to heart disease.

The apparent discrepancies between public and expert versions of risk have given rise to a series of psychometric studies (Slovic, 1992). For example, research has shown that a tendency by people to undervalue systematically the risks to which they are routinely exposed (because of their lifestyle or occupation), and to overvalue the seriousness of risks that are novel or could be catastrophic. Moreover, there appear to be significant differences between people's assessment of the risks to which they expose themselves and those to which they believe they are subjected by others. These perceptions translate into corresponding pressures in policy. People seem more likely to demand that automobiles be engineered to lower traffic fatalities than they would be to force themselves to drive those automobiles more cautiously.

The resulting tension between public and expert interpretations of risk has caused a problem for policy makers. If they base regulations on expert judgments – that is, keyed only to the statistical probability of harm – policies may be unpopular or even subverted, whereas basing policies on the public's apparent preferences threatens to make regulations arbitrary, unscientific, or too costly (Breyer, 1993). If the citizenry really is more tolerant of self-imposed risks than of risks visited on them by others, then there is an argument for reflecting this in public policy, whatever the 'actual' exposure to risk. Similarly, if, as Slovic (1992: 121) reports, the public is more concerned about certain 'dread' risks than other risks that experts hold to be of equal hazard, then maybe the cost–benefit equation has to be widened to take into account people's manifest preferences. Regulators find themselves confronting a tension familiar to liberal democracies, that between people's 'revealed' preferences and the recommendations supported by expert opinion.

Risk Expertise: The Reflexivity of Risk

These problems have become amplified in particular institutional contexts in ways that social science research has sought to explicate. Risk assessments have been developed, particularly by official regulatory agencies, so as to apply to statistically representative, or, in some other sense, 'average' people (Jasanoff, 1990). Calculations of how long it takes to evacuate an aircraft, and thus of the requisite number of emergency exits, the width of aisles and so on, are supported by evacuation trials, but these in turn depend on assumptions about the make-up of a typical passenger cohort. Similarly, arguments about exposure to pollutants have had to construct some notion of the average person as the unit for measuring the at-risk population (with, in many cases, the need to substitute the average risk animal for the average human). Yet this ideal type hardly exists in reality and may obscure threats to specific subpopulations. Women may be different from men; pregnant women are more clearly different. The young may differ from the elderly, the housebound from the active, and so on. These differences may prove to be far from 'academic' in particular contexts of exposure. For example, people who live near one of the UK's most controversial nuclear power plant sites, Sellafield, and who happen to favor a shellfish-rich diet may be exposed to a greater nuclear hazard than the average person, because of the way in which shellfish filter material from sea water. In this case, a seemingly personal behavioral choice interacts unexpectedly with other risk factors. In other cases, however, numerous background factors may act in synergy for the poor or socially disadvantaged, as in the case of American inner-city minority populations, who may be exposed to toxic pollutants from multiple sources (Bullard, 1994). In neither the UK nor the US, do standard risk-assessment methodologies, based on average characteristics, compute adequately the risks to especially vulnerable populations in particular cases. Indeed, technical risk assessment has tended to obscure the distributive implications of risk production. In this sense, risk is a social technology that reinforces existing structures of power (Winner, 1986).

Ironically, the great increase in formal assessments of risk has not so much diminished as contributed to the exacerbation of risk concerns (Beck, 1992[1986]). Given the complexities of risk assessment and the high stakes involved, it is understandable that risk assessment methodologies have been subjected to legal and other formal challenges (see Jasanoff, 1990). These proceedings have subjected risk assessments to critical deconstruction, questioning the precise basis for the choice of methodologies. Where these methods have had consequences injurious to some but not all sections of the population, the

procedure has been made to appear discriminatory. Environmental justice movements have formed to press the point that risk assessments of individual chemicals are not equivalent to a demonstration of the impact of a cocktail of pollutants. Communities experiencing extensive hazardous exposures – each element of which may be deemed not to be unduly risky on its own – argue that the overall impact of multiple sources is not well gauged by standard methodologies.

Furthermore, as Jasanoff (1990) has demonstrated, particularly in the US, the combination of adversarial cross-examination with the separation of powers and scope for judicial review of executive agencies has meant that extensive financial and intellectual resources have been directed at deconstructing risk assessments. Given all the complexities outlined above (the hypothetical nature of many risks, the difficulty of identifying an average case, the impossibility of most human experimentation, the need for surrogate measures, and so on), there has been no prospect of finding an incontestable scientific basis for defending particular risk assessments. The crowning irony has been that the language of risk has been developed in the hope of measuring and comparing risks objectively, but in practice risk assessments have repeatedly (though not, of course, always) failed to deliver a robust and compelling objectivity.

Sociological research has focused also on the strategic constructions of certainty and uncertainty associated with risk assessments. Thus, Wynne (1992) has argued that risks and probabilities are made up of many kinds of not-knowing, only a fraction of which (for example, uncertainties of extrapolation from rodent bioassays) may be acknowledged openly in formal risk assessment processes. In some cases, it is possible to establish a hierarchy of uncertainty, as between 'risks' and 'uncertainties': with risks one knows the odds, but with uncertainties only the general parameters of the problem. Most practical questions that science-in-public has to face, however, involve an additional kind of noncertainty. This Wynne terms ignorance. Ignorance refers to aspects of a problem that are consciously or unconsciously bracketed off, and commonly not further investigated. These may be issues that lie outside the disciplinary paradigms of the sciences in question and are thus in a sense necessarily, rather than perniciously, excluded from day-to-day research. Nonetheless, ignorance in this sense is a different form of not-knowing than mere uncertainty; it is not adequately captured by being treated simply as extreme uncertainty. Wynne's distinction was famously reaffirmed in a quite different context when the former US Defense Secretary Rumsfeld talked of 'known unknowns' (uncertainties) and 'unknown unknowns' (ignorance).

In principle at least, more knowledge might assist in handling these kinds of not-knowing. Uncertainties might be turned into risks. New understandings might clarify specific areas of former ignorance, though, of course, there is no prospect of ignorance being overcome in general. But, in addition, Wynne argues that there is a fourth consideration, which he styles 'indeterminacy,' resulting from 'real open-endedness in the sense that outcomes depend on how intermediate actors will behave' (Wynne, 1992: 117). In other words, the safety or reliability of systems with an organizational or human component is deeply dependent on how the systems are operated. By treating most systems as determinate, conventional risk-assessment practices typically adopt tacit, unexamined and untested sociological hypotheses about those social practices that are central to the risk-producing activities. Thus, evaluations of risks from potentially hazardous technologies do not depend only on the behavior of physical and biological systems (difficult to model though they may be), but also every bit as much on the behavior of plant managers, operators, and even those exposed.

Several insights into the sociology of expertise follow from these claims. First Wynne (1992) observes that experts, when faced with the need or chance to regulate in an area of noncertainty, are tempted to treat all forms of not-knowing as statistically tractable uncertainty, even though things of which they are ignorant cannot, by definition, be quantified. This process has been visible recently in relation to new forms of natural gas (methane) extraction, known as hydraulic fracturing or 'fracking.' Those in favor of fracking acknowledge that there are risks but argue that these risks are acceptable in the light of the benefits. Opponents of fracking tend to argue that we lack good understanding of the implications of fracking – in terms of geological settlement and contamination of ground water in the fracking process – so, the statements about risks are really claims characterized by uncertainty and ignorance (Wilber, 2012). Second, Wynne argues that the public may be significantly more expert than the scientists in relation to some of the matters covered by indeterminacy. His view, as expressed with Irwin, is that "science offers a framework which is unavoidably social as well as technical since in public domains scientific knowledge embodies implicit models or assumptions about the social world" (Irwin and Wynne, 1996: 2–3). In other words, insofar as expert assessments depend on assumptions about particular social, cultural, or occupational practices of lay groups, it is likely that these publics will be more expert in these matters than technical experts more distant from the relevant experiential insights. A clear example relates to recent attempts to manage urban air quality by using computer simulations of air pollutants. These simulations evidently depend on knowledge about the way gases move and persist in the air, but they also depend on assumptions about how potentially polluting factories and power plants, or even buses, are operated. Models routinely assume that plant managers do not exceed legal emissions-limits, but this view is not always shared by local respondents who put forward their own evidence about emissions and about the way plants are operated (Yearley, 2006).

A related body of research ties this manifestation of hazard within complex sociotechnical systems to features of organizational practice and culture. Thus, Perrow's discussion of 'normal accidents' (1984) makes the case convincingly that many hazardous occurrences are a routine (if often unpredictable) outcome of the interaction of the manifold technical and organizational components of modern power stations and production plants. Accidents are to be expected even if no particular accident is predictable. Subsequently, Vaughan applied associated insights to understanding the decision to launch the ill-fated Challenger mission (Vaughan, 1996). Of course, questions still remain about the extent to which organizational arrangements give priority to concerns for production, or for safety (Clarke, 1989), and many recent case studies show corporations placing the most value on production and profitability.

In sum, though risk discourse has been promoted by scientists and by scientific attitudes to the valuation of the natural world, it is clear that public experience of risk assessment has encouraged successful challenges to the official orthodoxy, as in the emergence of an environmental justice agenda, and that 'scientific' risk assessment has been undermined as it has been exposed (in courts and enquiries) to legal-rational reflection on the validity of the assumptions it necessarily makes. In response to such difficulties, official agencies commonly are left with no alternative but to demand 'more and better' science; yet there are few grounds for thinking that further research or rationalization will resolve the problems outlined above, particularly in innovative areas such as nanotechnology and synthetic biology where novel entities are intended to display wholly new attributes (Yearley, 2010). Ironically, social movement campaigners find themselves confronting a similar impasse. In opposing the establishment, they commonly produce counterclaims about health or environmental risks, yet find that related difficulties underpin their own risk claims. Such experiences often generate an ambivalent attitude toward scientific expertise (Yearley, 1992). These phenomena serve as a good example of what Ulrich Beck (1992[1986]) has termed "reflexive modernization." The institutions of modernity, notably the traditions of scientific analysis and legal fact-finding, have been turned upon themselves with deconstructive consequences. For Beck, this reflexive modernization is just one facet of the 'risk society' thesis, which portrays late-millennial industrialized societies as being unusually and overwhelmingly concerned with the distribution of risks and other 'bads.' In this view, social scientific interest in risk consists not so much in the study of societal responses to particular hazards; rather it is the key to characterizing the dynamics of contemporary society as a whole.

Risks and Cultures

Beck's thesis in its widest form asserts that the most modern risks (termed by others 'late' or 'high' modern (Giddens, 1991)) are reflexive in the sense that they are self-induced. Risks in the early modern period were external to the self-conscious control of social actors. Diseases would spread, bad weather would damage harvests, fires would consume urban areas as though under the influence of external, natural, or supernatural forces. Even if some of these risks were exacerbated by human interventions, the contemporary perception was that they were uncontrollable. In high-modernity, by contrast, risks such as the threat of disastrous nuclear reactor incidents are plainly the consequences of human activities (Beck, 1992[1986]). In this view, Victorian and early twentieth-century confidence about the progressive diminution of risk marks, in an ironic fashion, the transition from apparently external to societally induced risks. Scientific and technological developments are caught up in this reflexive pattern because modern risks are typically the result of technological ventures (nuclear power, ozone-depleting chemicals in the Earth's atmosphere); science and technology are involved in the cause, the diagnosis, and, with luck, eventual rectification of the problem.

Contemporary societies do still face external risks, for example, the possibility of a collision with an asteroid or other extraterrestrial body as monitored by National Aeronautics and Space Administration (NASA)'s 'Near Earth Object Program.' But the clear preponderance of contemporary risks, in the global north at least, has a strong – often dominant – human or societal component. One clear example is offered by smallpox. Previous smallpox infections had an 'external' quality. But after the disease was eradicated in 1980, the external risk effectively disappeared and inoculation programs ceased. However, the virus was maintained in at least two military research facilities, one in the USA and other in the then Union of Soviet Socialist Republics (USSR), purportedly so that research could be done on the virus to protect against 'weaponized' versions. Now, therefore, smallpox is no longer an external, but a societally mediated, risk since the threat could only come from accidental or illegal releases from these two facilities, from biological weapons produced with this virus material from the facilities, or from viruses synthesized in other laboratories. The risk is now focused on those who control the smallpox virus and much less on the viruses themselves.

Beck's overall analytical claim has been greeted with widespread enthusiasm by many social scientists, and the term 'risk society' has popularly been adopted. However, the details of his analysis have not met with the same welcome. For one thing, it is unclear how modern all present-day risks are. The incidence of mad-cow disease – eventually transmitted to humans – is thought to have arisen from the low-technology business of producing cattle feed from animal protein, specifically in the context of energy-saving, low-temperature process innovations. More significantly, Beck's favored examples – such as the risk of fall-out from the Chernobyl reactor explosion – have a primitively 'democratic' quality. On the face of it, the fall-out may descend upon the poor and wealthy alike. In that sense, the risk society is everyone's problem (Beck, 1992 [1986]). But as the environmental justice movement, particularly in the USA, has made clear, environmental 'bads' are still often distributed quite unequally along ethnic, gender, and class lines (Bullard, 1994). The risks of the risk society may not be shared as evenly as Beck implies. Finally, Beck has rather little to say about the reasons for persistent cultural differences in the salience of different kinds of risk, although it is clear, for example, that the framing of, and policy responses to, risks vary widely even between socially and economically comparable regions, such as Europe and North America (Jasanoff, 1986).

The relationship of risk and culture has been explored by the anthropologist Mary Douglas and several of her colleagues. Developing Durkheim's celebrated suggestion that religious cosmologies reflect social structures, Douglas proposed that cultural views of the characteristics of nature indicate as much about the reflected character of society as about the underlying features of nature itself. Carefree, individualistic, dynamic cultures tend to view nature as resilient and able to look after itself, while cultures which are precarious or worry about protecting their boundaries tend to view nature as fragile and in need of protection. Douglas subsequently developed this approach for the examination of risk in advanced industrial societies. A society's risk anxieties, in her view, relate as much to the cultural 'insecurities' of that society as to the actual extent of hazards (Douglas and Wildavsky, 1982). Douglas's cultural theory has proven difficult to test (but see Marris et al., 1998) and it raises a host of theoretical problems, such as the unit of cultural analysis and the sources of cultural change. However,

her approach does serve to underline the extent to which a culture's awareness of risks may be an imputation onto nature of more general cultural anxieties.

Finally, it is clear that not all modern risks arise from human interventions in nature. Though concerns about medical and environmental risks have increased conspicuously since the mid-1970s, worries about crime, immigration, internet security, financial markets and global social dislocation have also characterized the networked and industrialized world (see also Science and Social Movements). Risk anxieties can thus be inscribed not only to nature and to the human body, but also to the self-understanding of modern societies. As social life is increasingly conducted though on-line platforms, novel and unanticipated forms of risk (such as exposure to 'cyber-bullying') are created.

Risk: Social Psychological Perspectives

Abstract

The article presents current social psychological models that analyze how risk is perceived, represented, and communicated. This article focuses upon the recent interpretations of risk responses offered by social representations theory and by identity process theory. It also describes the mental models approach to risk reactions in individuals and the social amplification of risk framework for examining societal effects of actual or anticipated hazardous events.

Introduction

It is necessary to differentiate between hazard and risk even though they are often used interchangeably in ordinary conversation. Technically, a hazard is something that can precipitate undesired effects. Risk is the measure of the probability that a hazard will actually produce defined undesired effects. Risk essentially indexes the likelihood of a specified adverse occurrence. However, risk also has a second meaning in common parlance. It is used to refer to the magnitude of the detriment associated with an adverse event. Risk is used both to refer to the likelihood and the severity of an adverse effect resulting from a hazard. Take an example: a terrorist attack might be a hazard identified by a police force and they would seek to estimate the risk of the attack in terms of the chances that the attack will take place and/or the extent of the damage it might produce. The example is useful in highlighting a number of things about hazards and risk. What constitutes a hazard will depend upon your viewpoint concerning what is undesirable – the terrorists would not consider the attack itself a hazard, though the prospect of its failure would be a hazard for them. Debates about the existence (or otherwise) of a hazard are often in reality disagreements about what is or is not undesirable. The example also points to a common problem with risk – there are normally uncertainties associated with any estimates of probability of occurrence or magnitude of effect. Debates about risk levels (i.e., about the probability or magnitude of undesired outcomes) are often based upon missing, flawed, or contested information.

The ambiguities, conflicts, and complexity that surround hazards and risk make them ideal objects of social psychological examination. Both the conceptualization of the hazard and the estimation of the risk are products of social psychological processes in addition to any technical assessment. So, too, are the reactions to risk. This article describes some of the models that explain these social psychological processes. No one model alone will explain everything about representations and actions in relation to risk. Risk as an object of study requires consideration of how models interrelate and can be used in conjunction (Breakwell, 2007).

A risk representation is the product of a social psychological process in which a hazard is (1) recognized, (2) its characteristics identified, (3) the probability of its negative impacts occurring estimated, and (4) the magnitude of its effects hypothesized. A complex system of interacting elements brings about a risk representation. It is necessary first to consider the characteristics of a hazard, then to examine how its risk is conceptualized (the mental model), to go on to consider how emotions influence risk responses, and to assess the role of personal differences (particularly in cognitive style). Beyond that, it is important to explore how social influence processes inform the social representation of the risk and through this, mediated by identity processes, construct individuals' risk representations and behavioral choices. This article examines each of these elements in turn.

Characterizing the Hazard: 'The Psychometric Paradigm'

The 'psychometric paradigm' of risk perception provides one way of systematically examining the perceived characteristics of a hazard. The approach uses a variety of psychometric scaling methods (including magnitude estimation techniques, numerical rating scales, and attitude indices) to produce quantitative measures of perceived risk and perceived benefit/detriment. Typically, a large number of individuals are asked to rate a variety of hazards on a series of characteristics. Slovic (2000) and coworkers, over many studies, have shown that two orthogonal factors account for much of the variability in the correlations between ratings of hazard characteristics. The first is 'dread', which covers risk severity, uncontrollability, catastrophic impact, difficulty of prevention, plus how far its consequences are fatal, inequitable, threatening to future generations, not easily reduced, growing greater, involuntary, and personally threatening. The second is 'familiarity', which covers how far the hazard is observable, is known (to those exposed and to science), has immediate consequences and lacks novelty. This two-dimensional grid has been used extensively to compare the relative perceptions of different hazards.

Personal Variability in Risk Representations

The psychometric paradigm has offered a method for exploring how individuals perceive hazards. It is not a model that explains why the individual perceives the hazard in a particular way or why one individual differs from another in their perception of the hazard. Nor does it explain why a hazard may

be perceived differently across its life cycle. However, there are models of social psychological processes that can explain these personal (and social category) variations in hazard and risk perception.

There are significant differences between individuals and between different groups or social categories in the specific beliefs held about particular hazards. Some studies show women perceive greater risk levels than men (Slovic, 1997). Some studies indicate systematic ethnic or socioeconomic differences (e.g., Flynn et al., 1994), with people in more disadvantaged social positions typically perceiving risk to be greater. But more recent studies have suggested that these differences in risk estimates are explained better by differences in self-assessed vulnerability than merely by social category membership (Breakwell, 2007). This is true even though social category membership is frequently linked to both self-assessed and objective vulnerability.

Vulnerabilities can be psychological and/or material. Psychological vulnerabilities would include personal characteristics, such as enduring anxiety levels, cognitive style biases, and proclivity to avoid novelty. Material vulnerability would include limitations in control over exposure to the hazard, for instance, as a consequence of socioeconomic position. Vulnerability does not in itself explain all risk perception variation. For instance, differentials in knowledge will explain some differences in risk perception. But actual vulnerability, and, perhaps more importantly, subjective perception of vulnerability, can be a vital ingredient in determining the representation of a hazard that an individual or group would accept as appropriate or, indeed, help to create. For instance, the more vulnerable may generate a higher estimate of the risk of a hazard. They may do this because they hold a representation of the hazard that posits that it cannot and will not be controllable, perhaps because their own perceived vulnerability and inability to protect themselves undermines any argument that they will be protected from the hazard (Conti et al., 2011).

Perceived vulnerability, obviously, is not completely independent of the level of perceived risk. Even those who habitually regard themselves as relatively invulnerable and immune will recognize hazards that raise their vulnerability levels. So, in examining the relationship between vulnerability and risk representation one is always looking at a system with complex feedback routes.

This explanation for differences in risk perception assumes that people are actively engaged in the interpretation of hazards but they are constrained in how they do this by the psychological, interpersonal, societal, and material resources that they have available. Two psychological characteristics seem particularly relevant in shaping risk representations. The first, and most important, is self-efficacy and the second, a related but distinct concept, is locus of control. Both are related to psychological vulnerability.

Perceived self-efficacy reflects a person's belief in their capacity to perform in ways that give them control over events that affect their lives (Bandura, 1997). High efficacy is associated with greater cognitive resourcefulness, strategic flexibility, and effectiveness in managing one's social and physical environment. Belief in one's efficacy affects how much stress, anxiety, and depression is experienced in threatening or demanding situations. Those who think they can manage threats find them less aversive. Beliefs in efficacy also facilitate control over perturbing and dejecting thoughts. When faced with difficult tasks or problems, those low in efficacy focus on the difficulties they face not on the possible solutions to them. Low efficacy is associated with lower motivation to succeed and greater willingness to attribute failure to personal inadequacies.

Studies of self-efficacy in relation to risk estimation show consistent, if complex, patterns. The relationship between self-efficacy and risk taking depends on whether the risk is taken voluntarily or is imposed. In relation to voluntary risk taking, the link to self-efficacy appears to depend upon the desirability of the outcome of taking the risk. If taking a risk satisfies some desire or need, those high in self-efficacy are more likely to take the risk. For instance, with regard to high-risk sports, Schumacher and Roth (2004) found that those higher in self-efficacy took greater risks. However, if avoiding a risk serves some objective, then the highly efficacious are less likely to take the risk. For example, Siero et al. (2004) found those higher in self-efficacy were more likely to be able to quit smoking. In relation to imposed risk, the effect of higher self-efficacy is to motivate attempts to escape, avoid, neutralize, or eradicate the hazard. Floyd et al. (2000) showed that faced with a range of natural hazards, the self-efficacious would attempt adaptive self-protection.

Self-efficacy should also be linked to risk estimation. Since lower self-efficacy suggests a perceived inability to take action to protect oneself, it would be expected to be associated with higher perceived personal risk. This is supported. For example, Macintyre et al. (2004) found that males who feel self-efficacious with regard to the use of condoms perceive their personal risk of HIV infection to be lower. Other evidence suggests that efficacy may also be important in determining estimates of risk that are not personalized. Gifford and Heath (2006) found lower self-efficacy was associated with rejection of the existence of global warming and denial that it is artificial.

Locus of control (Rotter, 1966), a cognitive style bias, is also related to risk reactions. Internal locus of control (believing things happen as a result of one's own action) is associated with lower levels of risk taking in contexts where danger is salient (Miller and Mulligan, 2002) and with more adaptive precautions when the individual is at risk (McMath and Prentice-Dunn, 2005). There is also some evidence that where the hazard is subject to some degree of personal control, those with greater internal locus of control appear to be more accurate in their personal risk estimates.

Mental Models of Risk

Risk representations can be examined in a more holistic way than is offered within the psychometric paradigm. Fischhoff (1994) introduced the 'mental models' approach. A mental model usually has both an image of the hazard (its characteristics and their relationship to each other) and a story about the origin of the hazard. Sometimes it will include a narrative about the relationship between the hazard and the individual using the mental model (e.g., the extent to which the individual is at risk). The person's mental model of the hazard is elicited using a variety of techniques: think aloud protocols, recall measures, problem-solving tasks, and knowledge tests.

The methods entail significant engagement and active participation and thought from the respondents.

The mental models approach seeks to identify for a particular hazard both accurate and inaccurate beliefs that are held by a target population. These are then used as the basis for developing risk communication material that will correct misunderstandings. In this approach, the object is to bridge the gap between lay and expert models of the risk by adding missing concepts, correcting mistakes, strengthening correct beliefs, and minimizing peripheral ones. It is argued that people have an 'intuitive understanding' of risks and that they can be helped to a better appreciation of them and consequently be placed in a position to make more informed decisions if they are given new information in a format that is consistent with their initial belief system (Morgan et al., 2002). It is therefore crucial to map the initial belief system about the hazard that is the target for risk communication that is designed to change the risk representation and the behavioral decisions it services.

The mental model approach is founded upon the assumption that specific experiences and information will shape the mental model but the precise mechanisms whereby this occurs still need to be established. Experience of a hazard sometimes seems to be linked to increased complexity of the mental model. Wagner (2007), for instance, showed personal experience was associated with more complex mental models of flash floods and landslides. However, experience does not always enrich the mental model. Whitmarsh (2008) found personal experiences of environmental hazards do not affect perceptions of and behavioral responses to climate change. The role of mere experience of the hazard in shaping mental models is not understood. It seems likely that experience must be actively interpreted – given meaning – by other elements (e.g., social representational processes or identity processes) in the complex system that creates risk representations before it will be reflected in mental models.

Risk and Affect

The mental models approach is valuable because it requires the researcher to think about the complex system of interacting beliefs that underpins risk representation and decision making. It is also valuable because it highlights the significance of affect (emotions) in risk representation and response. Fischhoff (2007) suggested that risk communication can be unpersuasive when it fails to take into account the role of emotions.

The role of affect in risk representation is important (Slovic et al., 2004). This includes not just the impact of fear or anger as a response to danger (though these can be very important – see Fischhoff et al., 2005) but the subtler layers of affect that are attached to all our perceptions. Peters et al. (2006) summarize the four functions of affect in decision making (affect as information, as a spotlight, as a motivator, and as common currency). Finucane et al. (2000) argued that people use an 'affect heuristic' when making judgments. Representations of objects and events are imbued with varying degrees and forms of emotion, people allow these emotions to serve as a cue to decision making alongside any cognitive process that is involved (Slovic et al., 2005). Lowenstein and Hsee et al. (2001) found that, in a wide range of contexts, the immediate emotional reaction is more influential in determining choice than the rational evaluation of the options that may have been conducted beforehand. Peters et al. (2004) also found emotional reaction, and the strong affect-laden imagery associated with it, determines perceived risk rather than the reverse in their examination of reactions to nuclear power plants, radioactive waste, and radiation from nuclear weapons.

Predictions of some emotional reaction in the future can also influence risk representations and decisions. Regret is feeling sorry about an event or for a loss. Regret occurs after something has happened. However, risk researchers have observed that regret can work prospectively. They talk about 'anticipated regret'. People are motivated to avoid certain risks because they anticipate that they will feel regret later if they do take them. Zeelenberg (1999) showed it operates in choices concerning financial decisions, gambling, interpersonal relationships, and consumption. This work suggested that anticipated regret motivates risk avoidance but this is not mediated by heighten risk perception.

The role of affect can also be heightened or dampened. Gasper and Clore (1998) found that when people were made to pay attention to their emotional state their judgments were influenced by it, otherwise they were not, and, simply telling people to pay attention to their feelings – rather than to the facts – shifted the focus of judgments.

Social Amplification of Risk

The social psychological perspectives outlined above largely focus upon the individual in relation to the risk representation. The social amplification of risk framework (SARF) was developed specifically to explain how societal reactions to hazards occur. It describes both the social and individual factors that act to amplify or attenuate perceptions of risk and then generate secondary effects, such as regulatory changes, economic losses, or stigmatization of technologies. The SARF was proposed by Kasperson et al. (1988) and has been subsequently elaborated (Kasperson et al., 2003). The SARF proposes that hazards or risk events will have an impact not only through their primary physical effects but also, and often more importantly, through the way people and institutions (called 'stations' in SARF) communicate them to others. While 'stations' are often thought to be embodied in the media or official agencies, anyone can be one. Furthermore, transmission of signals is now multiplex; the Internet and social media sites taking an increasing role.

The act of communication requires that the risk is translated into various 'risk signals' (images, symbols, and signs) that will interact with a variety of psychological, social, institutional, or cultural processes and this will result in the intensification (amplification) or dampening (attenuation) of the perceptions of the risk and its manageability. Amplification refers to qualitative restructuring of the information about the risk – a change in its meaning or significance, not just a change of degree.

SARF is a social influence model of risk representation construction. While it has been criticized and a more differentiated taxonomy of amplification processes has been proposed (Breakwell and Barnett, 2001), it nevertheless serves

to emphasize that a hazard becomes imbued with meaning as a consequence of the system of social influence processes within which it is embedded. Moreover, SARF suggests that the consequences of the hazard are themselves in part determined by the reactions of those engaged in communicating about it. Yet, as originally proposed, SARF is descriptive rather than predictive. For instance, it will not predict under what conditions intensification or attenuation will occur.

Following studies of a series of risk events using the SARF approach, Breakwell and Barnett (2003) suggested that there were discernable regularities in the way in which amplification processes worked that could provide the basis for developing it into a more predictive model. They highlighted the roles of what they labeled 'hazard sequences', 'hazard templates', and 'hazard negotiations'.

Hazard sequences refer to a simple notion: any one risk event is often represented or conceptualized as part of a sequence of risk events that share common features. So, for instance, a train crash will be viewed within the frame of a series of other train crashes. The existence of the hazard sequence allows the new risk event to be located in terms of its severity and meaning because it offers the backcloth of knowledge about similar events in the past. Reference to other past risk events can also provide the emotional connotations necessary to achieve either intensification or attenuation.

Hazard templates are an extension of the notion of hazard sequences. When a new risk event occurs the way it will be represented will be determined by the 'templates' that already exist for the representation of that type of risk. The template will provide ready-made phrases to be used about it. It will provide common explanations for the origin of the risk event, the individuals, groups, or institutions who should be held responsible, the forms of remedial or punishment action that should be taken, etc. The form of the template is roughly common across hazards but the substantive content will differ widely. So, for instance, the content of the template for a multicar smash on the highway in fog (e.g., reckless drivers, driving too close and too fast; poor signage; overcrowded highways causing increasing occurrence; need for improved driver training and highway control; efficient response of the emergency services who worked tirelessly; etc.) is different from the content of the template for an outbreak of food poisoning in a hotel (e.g., poor hygiene, poor management, inadequate regulatory controls, increasing incidence of such cases, etc.). Nevertheless, some underlying similarities emerge: the cause, the significance, the responsibility, and the redress. The hazard template is the basis for the specific mental model of the risk. These templates are commonly used by the mass media to structure their stories but they are also the frameworks that lay people use when they come to talk about a new risk event. They appear to have a risk vocabulary and rhetoric that is built upon understandings and expectations of the way different hazards work. These understandings and expectations are shared to varying degrees.

Hazard negotiation is the concept introduced to acknowledge that understandings will not always be totally shared. When 'stations' find that they are broadcasting messages about a risk event that are at variance with each other, there is scope for them to attempt to negotiate a common interpretation or, if this proves impossible, at least to seek a compatible set of interpretations. Hazard negotiations can range from the formally structured exchanges with clear rules of engagement to the informal free for all. They are rarely, irrespective of format, conflict free. The objectives of parties in the hazard negotiation will be driven by their self-interest. To reiterate all aspects of the processes of amplification (including hazard sequences, templates, and negotiation) will play a part in determining the mental models that individuals hold about a hazard.

SARF itself is silent about the nature of the processes that determine substance, form, or acceptance of risk representations. The work on hazard sequences, templates, and negotiations goes some way to rectifying this. However, there are two other approaches that have been used: social representations theory (SRT) and identity process theory (IPT).

Social Representations of Risk

SRT (Moscovici and Farr, 1984), one of the major social psychological theories of social influence processes, can provide the basis for explaining how an individual may acquire a representation (or mental model) of a hazard. According to Moscovici, social representation operates with two prime processes: objectification and anchoring.

Objectification entails translating something that is abstract into something which is almost concrete, gaining a density of meaning that ultimately makes it a common and 'natural' part of thinking about the object. Anchoring entails categorizing a new object into preexisting cognitive frameworks in order to render them familiar – reducing the strange and unfamiliar object to the level of an ordinary object set in a familiar context.

SRT may be particularly relevant to explaining why particular mental models of hazards evolve because it was initially developed to explain what happens when people are faced with having to make sense of, or give meaning to, ideas or data that are novel to them, under conditions of uncertainty and where claims are contested. Plainly these are quintessentially characteristics of the initial interface between people and information about hazards. Indeed, it might be argued that encountering a newly identified hazard inevitably triggers social representation processes. Castro and Gomes (2005) illustrated this through an analysis of the way the media discussion of genetically modified organisms developed in the Portuguese newspapers between 1999 and 2001. They showed anchoring in prior ideological systems concerning agriculture and scientific innovation.

The processes of objectification and anchoring could account for the structure often evident in mental models of hazards held by lay members of the public. Frequently, systematic empirical investigations expose lay representations of a novel hazard that are characterized by objectification (the abstract properties of the hazard being translated into commonly understood metaphors or represented through tangible, if tangential, exemplars) and by anchoring (given meaning through association or through claiming similarity with other types of explanation that are more familiar). SRT would suggest that the representation that is constructed of any hazard will be determined by the proclivities of the individual for particular forms of

objectification and anchoring. However, SRT would emphasize that the representation produced of any hazard is not idiosyncratic or purely individualized. SRT states that objectification and anchoring are not individual processes. They are processes that normally involve social interaction and the establishment of shared meaning and consensus through communication among people.

If mental models of hazards are generated through processes of social representation, they will be substantially shared by members of discrete subcultures. This does not mean that all members of the subculture would hold absolutely identical mental models of a hazard but rather that their mental model would share certain common core elements. SRT suggests that subcultures (and social categories and groups) shape the social representations that they develop to serve their self-interests. Thus the construction of a mental model of a hazard by a subculture will be purposeful, motivated to achieve particular objectives. Willis and DeKay (2007), for instance, showed how differences in stakeholder group membership predicted ecological risk representations. Support for climate change policy is particularly affected by socioeconomic factors (Dietz et al., 2007). Of course, the media are particularly active in creating social representations of climate change and offer subcultures exposure to competing risk representations.

There is overwhelming evidence that risk in general is fertile ground for contested social representation and competing mental models of hazards are common. This SRT interpretation of the genesis of the representation of hazards has significant implications for explanations of how intensification or attenuation in SARF might work. It suggests that the subcultural base for any individual's representation of a hazard will influence their susceptibility to any reframing attempts, including official interventions aimed at changing risk perceptions.

Identity Processes and Risk

Although social representations have been defined at one level as being a widely shared set of beliefs, it is not the case that beliefs are accepted and used by individuals in their entirety. Among alternative competing social representations, the hazard representations of which an individual is aware, will accept, and may use will firstly depend upon the significance they have for identity. That is, the content and usage of a social representation can be predicted in relation to its likely impact upon the demands of individual identity requirements.

IPT (Breakwell, 1986), which links social representation and identity models to predict risk perceptions, proposes that the extent to which any message about a hazard will be received and incorporated into an individual's belief systems is affected by the ways in which this may threaten the individual identity. IPT argues that identity requirements are important determinants of awareness, understanding, acceptance, assimilation, and salience of social representations (and, indeed, of mental models of hazards). IPT postulates that individuals are motivated to achieve certain characteristics in their identity structure: continuity, distinctiveness, self-efficacy, and self-esteem. These four motives vary in their relative and absolute salience over time and across situations. A threat to identity occurs when these motives cannot be satisfied. If they find that esteem, continuity, distinctiveness, or efficacy are threatened, individuals will use a variety of strategies to protect or regain them.

IPT has now generated an extensive series of studies, which illustrate that individuals in the same social category will accept and use (i.e., reproduce or act in accordance with) a particular social representation to differing degrees depending upon its potential impact upon their identity esteem, continuity, distinctiveness, and efficacy. Many of these studies have concerned social representations of hazards. For example, individuals will reject social representations of their local environment as being polluted (despite objective evidence that it is) if attachment to that place features as an important aspect of their personal sense of distinctiveness (Bonaiuto et al., 1996). Such studies would suggest that use and acceptance of social representations generated in the course of social conflict or controversy are most significantly mediated by identity processes. Many environmental hazards generate such 'polemical' social representations of hazards, created by agencies or groups in conflict (Masuda and Garvin, 2006). Under these circumstances the social representations of hazards that the individual chooses will be highly influenced by identity requirements. Essentially, individuals will resist acceptance or use of social representations of hazards if they threaten identity continuity, distinctiveness, self-esteem, or self-efficacy. Of course, self-efficacy has been highlighted earlier as a predictor of risk representations.

Conclusion

Some of the social psychological approaches that describe how individuals and societies construct risk representations have been presented. The psychometric paradigm and the mental models approach have highlighted methods for exploring the structure of hazard characterization and identifying personal variation in risk representation. The work on vulnerability, particularly psychological vulnerability associated with cognitive style and affect, shows that individual differences in risk representation are in part explicable in terms of personal characteristics. Used in conjunction, SARF, SRT, and IPT offer a way of understanding the social processes involved in shaping the way certain risk representations evolve and who will accept, use, and act upon them. Together the three approaches offer a route into an integrated social psychological model of risk. The models encompass consideration of the cognitive and affective processes that shape the individual's risk representation. They also examine the social processes that create the dynamic milieu within which the individual thinks and feels about the hazard. The important thing is that taken together these models of risk construction are capable of describing individual cognitive, affective, and oretic factors as they interact with societal structures and ideologies to shape risk representations and behavior.

Abstract

Ritual is rule-governed action, which is repeated on special occasions. It may sometimes be regarded as sacred and part of religion, but at other times may be seen as secular. It may also be accompanied by prayer or other forms of regularized verbal expression. It is commonly associated with specific places, such as temples or shrines, and with particular bodily movements or such collective events as processions. Although knowledge of ritual is handed down from one generation to the next, it may also undergo change in its form and effects. It can be studied as part of biocultural evolution.

Sacrifice could well be the historical starting point for anthropological definitions of ritual. It is the practice that is central in early anthropological studies of religion by Robertson Smith, Frazer, and Tylor. More abstract notions of ritual came later, sometimes dissociated from religion and expressing other social relationships. For Durkheim (1964), ritual is how religion makes society. It is social activity falling within the domain of the sacred. The sacred is opposed to the profane, which does not contain ritual action. Leach (1954), however, rejects Durkheim's hard and fast distinction between sacred and profane, preferring to see these as aspects of social actions lying along a continuum. At one end are those actions that are largely technical and profane, while at the other are those, which have no technical functions and are largely symbolic, aesthetic, and sacred. Most actions in between these two poles have aspects, which are both sacred and profane.

Ritual in Leach's sense is, then, by no means confined to ideas of the sacred. By removing ritual as exclusively to do with the sacred, Leach is able to broaden the definition of ritual. He thinks of it as a message-making kind of activity, and so as an aspect of any kind of behavior in which repetitive or customary acts signal messages. Handshakes or wearing a tie in the office are as much forms of ritual as a priest praying to ancestors at a shrine. So-called magical and secular acts are, therefore, both communicative and both are examples of ritual action, Ritual for Leach is, then, a way in which humans communicate with each other in different aspects of their social structure.

Thus, we may be perfectly aware of social class or status differences and even be able to talk about them discursively. But we still signal or symbolize these differences in a number of short-cut ways, through distinctive accents, differences of dress and lifestyle, and even bodily movement and gesture.

Sometimes we are not so conscious of the differences our ritual behavior communicates, and sometimes the differences exist simply through lack of knowledge of how to behave on, say, a formal occasion. In other words, the sociostructural approach argues that ritual action does not occur in a political and economic vacuum: politicoeconomic interests are always involved to some degree, even if sometimes minimally. Leach also claimed that separating ritual from myth was nonsensical for myth 'says' in words what ritual 'says' in action, a view which relates to but is somewhat different from Malinowski's view of the two as separable but sometimes linked: with rituals being accounted for or explained in myths. In accepting the idea that ritual is communication, Bloch (1974) proposes that its repetitive, formalized nature precludes argument and so reinforces the authority of those who control and advocate the ritual. Other scholars counterargue that onlookers and participants in a ritual may have different ideas as to how it should be conducted, and so change the interpretation, meaning, and social effect of the ritual.

A second approach to the study of ritual emphasizes its logical qualities. Here, ritual communicates fundamental ideas that may be specific to a particular culture, or that may even be universal. It is an approach that owes much to structuralism in anthropology, which is predominantly associated with the work of Lévi-Strauss. It turns on the idea of culture as organized through binary oppositions.

Thus, Needham (1961) has suggested that, when a male diviner or shaman uses his left hand to throw the cowrie shells, which he or his possessory spirit will interpret in order to understand the cause and course of an illness or misfortune, he is reversing a kind of natural order. For men are normally associated with the right hand and women with the left. But since diviners fall outside the realm of normal human capacities, being able to see what other humans cannot, it makes logical sense to reverse the equation of maleness with the right hand. There is no functional explanation for these kinds of ritual reversal for they are governed by proclivities of the human mind.

That said, local political and economic circumstances can sometimes take up these proclivities and harness them to a cause. Thus, prophets leading religious movements may communicate their power and distinctiveness through rituals, which reverse normal expectations. Many other kinds of ritual behavior, like some beliefs and myths, achieve their communicative effectiveness by being considered natural.

Now, while it is true that ritual may be thought of as communicating messages about status or about the way the human mind works or how the world is, it varies enormously in the degree to which it is elaborated. After all, a handshake can hardly compare with a full-scale ritual investiture of a monarch spread over days and involving thousands of people and lavish expenditure. To call both these kinds of activity 'ritual' clearly leaves out much of what is special to the latter. Similarly, some hunting and gathering peoples such as the African Mbuti forest dwellers do not perform elaborate rituals, while other African groups noted for their masquerades do.

Peoples do, then, seem to differ in the relative amounts of ritual, which they perform; although, in making this claim, there is a dangerous Eurocentric qualitative assumption that the significance of ritual is measured by the amount of time, materials, and people involved. Who is to say that an apparently slight activity, taking only a moment and few resources, may not in fact 'say' much more than a drawn-out ceremony of great proportions whose influence on people is in fact limited? Nevertheless, it is a useful if provisional starting point of analysis to try and understand how variations in the complexity and lavishness of ritual reflect those of social organization and cultural logic.

Arising from this approach is another, which recognizes that as well as communicating messages about the current social structure or about fixed properties of the human mind, rituals also change things or enable changes to take place. We may call this third, the transformational approach to ritual. For Van Gennep (1965), the rites of passage as marking changes of status in the human life cycle – for example, birth, puberty or adolescence, marriage, first child, first grandchild, and death – could be broken down into three phases: separation, liminality, and incorporation. In other words, the individual undergoing the ritual must first be separated from the community of which they are a member, perhaps by removal of the head hair or some other bodily alteration. They then enter the liminal phase in which they are regarded by members of the community as outside and beyond normal human society. This is the phase in which there is transition from one status to another, for example, from child to adult, bachelor to husband, etc. Van Gennep saw this as a period of death, i.e., of the child, and of rebirth, i.e., of the adult. It is a theme elaborated in many later studies that showed the ritualization of death as the condition of new life or regeneration. The third and final phase is when the individual is reincorporated in the community, now no longer a child, but an adult with the rights and duties expected of this new status.

Van Gennep saw these features of rites of passage as also typifying other kinds of transition in addition to those of the life cycle, such as the seasonal or other movements of groups, fertility rites, and entering and leaving dwellings, special days or months, and cult societies. Victor Turner (1967) made the notion of liminality central to his work on ritual, extending to the idea of antistructure, by emphasizing the rejection of society on the part of people undergoing transition or in a marginal state, and also communitas, by which he meant the way in which people on ritual occasions temporarily transcended their normal, everyday social conflicts and cleavages and emphasized their common humanity. In addition to the life crisis rites of Van Gennep, Turner further distinguishes rites of affliction, which are held to reverse the effects of, for example, women's infertility, crop failure, sickness, and other misfortunes adversely affecting the lives of people living together in a single village or other dwelling. They also enable people to move from one state to another, although not as part of the human life cycle, but more as part of the unpredictability of the human and social condition in which conflicts and contradictions are not so much represented in ritual as presented, addressed, and then redressed, an approach which thus builds on and advances that of Durkheim.

A subset of this approach might conveniently be called Marxist in the sense that social inequality and exploitation of working by a ruling class is presupposed.

A Marxist approach would, for instance, claim that the official, media, and public ritual attention devoted to the British royal family evokes ordinary people's unquestioning compliance and loyalty, to the extent that they cannot see that the institution of royalty in fact underpins the system of landed privilege that defines an aristocracy and provides an imitative model for other ruling and bourgeois classes. The 1990s in the UK saw an extraordinary rise in the degree to which the media and many of these same ordinary citizens began to question the worthwhileness of royalty. Questions were raised as to whether this was an example of royal rituals losing their capacity to retain subjects' loyalty, a kind of demystification of ritual. Or perhaps it was a case of the different interpretations of ritual enabling social change to occur. In any event, by the 2010s, public attitudes to royalty warmed again, as instanced especially at royal weddings such as that of the young heir to the throne, the Duke of Cambridge and his popular 'commoner' bride, the former Kate Middleton.

Royal rituals have been a common focus of anthropological analysis, in which their transformative power has been highlighted. Gluckman (1963) was dissatisfied with studies of royal and other rituals, which saw them as simply affirming the sovereign's authority and the solidarity of the society under his rule. Using the example of the Swazi *Incwala* royal ritual in southern Africa, Gluckman claimed instead that its socially cohesive function was only possible after it had revealed the society's internal conflicts: such conflicts had to be addressed before they could be accepted as part of the normal social process.

Beidelman (1966) criticizes Gluckman's overreliance on social conflict as needing to be expunged through royal rituals, and argues for a view of them as marking out the divine or mystical properties of kingship, so providing the king with legitimate recognition to reign over his subjects.

This example moves us on to a fourth approach to ritual, which is to see them not necessarily as achieving a particular social or logical function, but as expressive in and of themselves. Beattie (1966) attacked attempts to explain rituals as practical and intellectual attempts to solve problems. Rituals draw instead on people's human predilection to engage in creative thinking, sometimes through culturally enjoined associations of ideas, and were thus closer to art and drama than to technology or science. Rituals in this sense do not 'do' things so much as express human dilemmas, symbolically and often under some kind of duress. They cannot be reduced to questions of whether they are rational or irrational, or true or false propositions, any more than aesthetics can be explained in these terms. In many respects this explanation of ritual as expressive rather than functional reproduces Leach's distinction between technical and aesthetic acts as occupying two extreme poles of a continuum between which they are both aspects of any activity. Nevertheless, expressed in the way that Beattie did, it freed anthropologists from having to seek practical explanations for a particular form of ritual behavior. If a ritual appeared to perform a particular function in society, this could better be regarded as an unintended consequence of an activity whose participants did not have such consequences

in mind. Thus, it may well be that the British royal rituals for a long time had the effect of persuading the public to accept the stratified status quo as rightfully headed and legitimized by the monarch and the monarch's family. It may well be, moreover, that politicians and members of the ruling elite recognized, seized on, and developed this effect, so turning consequence into purpose. The expressive here becomes instrumentally effective.

However, not all that which we understand as ritual behavior can be interpreted in this way. People throughout time do not normally calculate in advance what might pass as effective ritual, nor indeed separate ritual as a social category from nonritual; nor may we assume that what we define as rituals always have significant social and intellectual consequences.

This leads on to a fifth approach that derives from the widely held idea that ritual is principally performative and not necessarily aimed at any other than satisfying its own rules of procedure. Geertz's analysis of the Balinese state as theater is an example (1980). Another example is a study of the Indian Jain rite of worship by Humphrey and Laidlaw (1994). Their intriguing starting point is the fact that in some societies, people may distrust ritual practices as being empty or false, and yet continue with them. Similarly, noting that for many people, religion and ritual are seen as going together, they also refer to the way in which practitioners of some religions turn on their rituals as unworthy and even frightening. The European Reformation attempted to strip off from Christian religious belief what were regarded as some unacceptable ritual practices, as Wahabi reformers in Islam are doing today.

By contrast, some argue that ritual is good for religion and humanity. Mary Douglas (1973) drew some of her own ideas from trying to understand the rejection of ritual in the Catholic Church by many of its senior adherents who also, for good measure, dispensed with the Latin language as if transparent clarity was all that mattered, over and above the expressive power of faith.

The disjunction between religion and ritual led Humphrey and Laidlaw (1994) to suggest another disjunction, which is that between the intention of actors in ritual and the ritual actions themselves. Sometimes intention and act fit, and sometimes they diverge irretrievably, but sometimes they are aligned.

Such lack of fit is not to be understood as the result of mistakes in intention and performance, but as evidence of the way in which ordinary actions may become endowed with the quality of ritual. For these authors, ritual is a quality that actions take on: they become ritualized. While everyday actions are intrinsically intentional, ritual acts enter a kind of phenomenological space freed of such everyday intentions, and, paradoxically, are 'intended' to do so. There is here a 'ritual commitment,' a notion close to that expressed in a classical study of ritual by Gilbert Lewis (1980). Humphrey and Laidlaw (1994), moreover, oppose the idea that ritual is necessarily communicative and expressive of messages and beliefs.

One is here reminded of Sperber's (1975) view that symbols do not intrinsically mean anything. Rather it is people who interpret a symbol as such, and who thereby give it meaning. The concept of communication here has to be established. It may mean one person making an assertion and expecting a response from the hearer. Or it may simply mean making a gesture or uttering a conventional phrase ('It is hot today'), for which no response is expected and which is therefore really a form of what has been called phatic communion, a device to secure solidarity with another person. Rituals may sometimes communicate but, as Rappaport (1979) points out, so do many other kinds of phenomena, and by privileging its expressive functions we miss what is otherwise distinctive of ritual.

The view that ritualization is a process by which actions become endowed with a ritual quality, shares something with Gerholm's (1988) notion that ritual is, so to speak, partly made up as it proceeds. That is to say, there are at least some kinds of ritual for which precise textual rules do not exist or which have been forgotten, with the consequence that participants have little more than a sense of ritual occasion or commitment and endeavor to convey that sense in actions and words, inventing and borrowing as much as they can. This ushers in a query as to how much ritual depends on precise wording as well as actions. A Christian prayer depends heavily on personally composed as well as prescribed verbal forms, and is firmly regarded as ritual. But rituals are also organized through spatial orientation and bodily positioning. The many different kinds of Islamic prayer are also personally or formulaically verbal, but crucially require orientation to Mecca, while a particular class of prayer or devotion called *salat* is made up of a complex sequence of prostrations as well as recitations (Bowen, 1989). In the event of the mosque imam taking on the recitations on behalf of the congregation, the prescribed bodily actions become the individual worshipper's ritual responsibility and must be repeated if they are performed incorrectly. Parkin (1992) has argued that it is not always the case that the verbal is important in ritual, while set spatial directions and orientations, and bodily gestures, movement, and positions are what mark off and so fundamentally characterize ritual. Bell (1997) also points to the way in which the disciplined body in rituals has to obey formal rules regarding its posture and positioning.

Finally, running throughout the various perspectives on ritual from Tylor to present day is its association with sociocultural change and evolution. Most often this is implicit, as in ethnographic demonstrations of how ritual can reflect, bring about, or deny social change while itself undergoing transformation. Sometimes ritual is presented explicitly as the template and instrument of biocultural and cognitive development as in the work of Barrett (2004), Boyer (2002), Cohen (2007), and Whitehouse (2004). Here religious beliefs and their ritualization are based on innate or intuitive cognitive dispositions, which are developed along with increasing sociocultural complexity.

A challenge is to avoid essentialist definitions of ritual, which seek to set up criteria that must be met before this label can be applied to an activity.

Phenomenologically, ritual is to do with the paradox of being both the agent of an action, but also being taken along by this same action. It presupposes being able to move within an action: from citing its purpose to having no need, wish, or clear idea of what it is about, and yet valuing it. Nevertheless, ritual must have some kind of structure, the most elemental of which is that individuals alone or with others take up positions with regard to each other or with regard to objects, experiencing such positioning as unlike any other.

Abstract

Archaeologists approach ritual and symbolism from a material basis: through the places, things, and trace residues left behind as a result of human action in the past. Where historically, archaeologists adopted definitions of ritual, religion, and symbolism that were rooted in structuralism, today they increasingly draw on the semiotics of Charles Sanders Peirce and practice theory, broadly rooted in the work of Michel de Certeau and Pierre Bourdieu, to interpret materials in terms of action and meaning-making in the past.

Archaeology of Symbolism and Ritual

Archaeologists derive their understandings of the aspects of human social life through material traces: the spaces, objects, and residues created when people carried out activities at some point in the past. As a result of this material mediation of knowledge production, archaeologists approach topics involving ideas or cognition in distinctive ways. In recent decades, this has involved a move away from the identification of structures or categories reflected in things or features of things, to an examination of how material media shaped and were shaped in actions that we can understand as meaning-making. Archaeologists interested in meaning critique reliance on structural linguistic models rooted in the work of Ferdinand de Saussure, and advocate broader semiotic models derived from the work of Charles Sanders Peirce. A major focus of archaeological research on symbolism has been the linked domains of ritual and religion. Religion, understood as belief, was initially thought to be difficult if not impossible for archaeologists to investigate. Ritual, understood as a behavioral aspect of religion, in contrast was defined in ways that potentially allowed identification of material evidence, such as distinctive spaces where rituals took place, and objects used in ritual practices. Increasingly, archaeologists debate the dichotomy between religion and ritual, the nature of any relationship between them, and the ease of distinguishing ritual action from everyday action. While many archaeologists continue to explore ritualized practice, others have turned to investigation of the experiential dimensions of religion, or examine the material settings associated with known world religions, where it is imperative to relate material spaces and objects to concepts recorded in texts.

Archaeology of Symbolism

Symbolism requires representation of one thing, often more abstract, by reference to another, often more concrete. Relations of substitution are thus fundamental to the definition of symbols. This implies that symbolizing requires a conscious act of reference to associate meaning and the thing taken to carry meaning. Most archaeologists have, until relatively recently, based their understanding of the relations of reference involved on a structuralist model of symbolism rooted in the work of Ferdinand de Saussure (Preucel, 2010). This approach saw symbolizing as the making of an arbitrary relation between a concrete form (a vehicle) and a usually more abstract meaning intended by the producer of the arbitrary symbolic relation. The task of analysis thus became to decode the intended meaning, making archaeology of symbolism dependent on a claim to reproduce ancient thought.

Drawing on information theory, archaeologists treated symbols conceived in this way as messages intended to communicate clear meanings (Wobst, 1977). If symbols were media to convey messages, not just arbitrary meanings, then there would have been strong social pressures, and even adaptive advantages, to having shared interpretations of their meanings. The application of communication models to the archaeological study of symbols facilitated the development of an archaeological theory of style, the definition and interpretation of sociopolitical status badges (items that convey rank or role, such as a crown), and the interpretation of differences in material culture as markers of ethnic boundaries and cultural identities. However, ethnoarchaeological research demonstrated that the degree to which the use of common material forms conveys either a conscious or unconscious intent to associate a form and meaning is highly variable (Hodder, 1982a). Arguably, only those instances where a conscious connection was forged between vehicle and meaning could properly be considered symbolic. An example would be artifacts interpreted as status badges created as deliberate signs of rank, such as a scepter or crown. Where artifact style (the manner of making something that produces a distinctive appearance of similarity in a series of things) had been viewed, using communication theory, as deliberately intended to convey a sense of identity, ethnoarchaeological critics found little evidence of the necessary intent to signify belonging that would have justified this under the model of the arbitrary symbol.

Critics of the model of archaeologically recovered objects as vehicles carrying preexisting meanings developed starting at least as early as the 1980s (Robb, 1998). Critics argued that symbolic meaning, rather than being installed in a symbol by the intent of the original maker or user of a symbolic object, was negotiated, shaped, created, and recreated through the use of cultural forms, including the durable ones recovered by archaeologists. This view of symbolism requires attention to contextual relations in order to understand how symbolic meaning was produced. Archaeologists developing these

critiques expressed uncertainty about their ability to understand the specific meanings symbols had for past actors, yet they routinely made arguments about the deployment of symbolism as part of strategies of actors and factions within past societies.

Growing from this understanding of meaning as emergent from the act of interpretation, contemporary archaeologists have explored the three-part model of the sign offered by Charles Sanders Peirce (Bauer, 2002; Joyce, 2007, 2008; Lele, 2006; Preucel, 2010; Preucel and Bauer, 2001). For Preucel and Bauer (2001: pp. 88–89) the critical shift is from the two-part relation of signifier and signified in the Saussurean sign, to a three-part relation of Sign, Object, and Interpretant in the Peircean sign. The third part of the Peircean sign, the Interpretant, places meaning-making in historical and contextual circumstances, as an active process of creating relations among people and things. An interpretant actively links the representamen (sign, concrete object that represents) to an object. Consequently, "sign relations are neither linguistic nor completely arbitrary … the representamen's relation with an object represented for and through an interpretant is not necessarily arbitrary" (Lele, 2006: p. 50).

This latter point has become especially important in the contemporary exploration of symbolism in archaeology. While an arbitrary relation of representamen and object in a symbol is one mode of meaning-making, two other modes can be defined where the relationship is not arbitrary, and thus potentially open to analysis without access to the intentions of the original maker of a symbol. These two additional forms of semiosis (meaning-making) explored by Peirce are iconicity and indexicality. Indexicality has been particularly productive in archaeological analyses (Joyce, 2008; Lele, 2006; Preucel and Bauer, 2001). The representamen of an indexical sign is existentially connected to the object of the sign, rather than being simply conventional: the classic example is a footprint interpreted as a sign of the person or animal that produced it. A rock painting in the form of a handprint, even if painted as a design rather than directly printed by dipping a hand in paint, can be understood as indexing, or pointing toward, the presence of a human being, as a trace of a person who had been present at this place. From this indexical relationship, archaeologists can propose that the hand print might have been interpreted as a sign of a human presence, rather than as an entirely arbitrary symbol.

Using the concept of indexicality, archaeologists always can work from some form of connection between a material trace and a cause to begin to suggest that meaning-making took place, and even to begin to suggest a range of meaning that might have been in play in the past. Preucel and Bauer (2001: p. 90) cite Richard Parmentier's discussion of archaeological analysis of pottery style as an example. Every pot recognizable as in a specific style indexes a set of repeated traits that make up the style, which can through interpretation point to an existential identification among the makers of the different pots, developing their skills and manner of making pots together. This use of indexicality avoids the problematic assumption of self-conscious, intentional identification through style critiqued by earlier analysts (Hodder, 1982b). It also makes clear that archaeologists identifying a shared style as evidence of a shared identity are creating a sign in the present using things made in the past. Potentially, the same kind of interpretation could have occurred among the makers and users of these pots – although this cannot be certain. Parmentier's model of potential but not automatic identification through shared style better matches the evidence gathered through ethnoarchaeological studies.

Iconicity is also important in archaeological analyses of symbolism and meaning. Iconic signs create meaning by the recognition of resemblance between the representamen and object. What constitutes resemblance is culturally specific. Preucel and Bauer (2001: p. 90) note that for Parmentier, legibility of different pots as being in the same style is a product of their mutual resemblance, an iconic sign. Archaeological analysis of graphic images routinely relies on iconicity, usually without explicit consideration of how meaning is being inferred. An example would be the analysis of small-scale objects made of clay, figurines, routinely identified as representing human or animal bodies even when only very general symmetry provides the ability to define a head and body, and when most bodily features are not represented (Joyce, 2007). This example shows that the identification of resemblance that underpins iconicity also requires an act of interpretation. Again, the use of a Peircean model clarifies that both the modern analyst and the original makers and users of any object carry out acts of interpretation, which may or may not result in congruent meanings.

Archaeology of Ritual

Archaeologists have always identified some things as evidence of ritual. Beginning in the 1950s explicit concern was addressed to the methodological status of archaeological inferences concerning belief and meaning. Interpretation of ideational systems, including religion, was viewed as more problematic than other topics, such as economics and subsistence. As early as the 1960s, some archaeologists argued that ritual and symbolism were no more difficult to attempt to analyze than other topics, questioning the analytical separation of material and ideational aspects of society. Since the 1980s, archaeologists influenced by practice theory have attempted to demonstrate that the archaeological analysis of ritual benefits from explicit attention to human agency. This includes discussions of the experiential dimension of religion, whether conceived of structurally, cognitively, or in terms of biocultural effects. Most recently, archaeologists studying world religions have emphasized the need to create an archaeology of religion, independent of an archaeology of ritual.

The 'Ladder of Inference' and Processual Approaches

In 1954, Christopher Hawkes (1954) proposed that in the absence of texts, archaeologists were constrained by a ladder of inference which governed the probable reliability of their explanations. According to the ladder of inference, some topics were more tightly circumscribed by pragmatic considerations. As a result, archaeologists were likely to recover a greater proportion of the evidence necessary for understanding these topics, and their explanations were likely to suffer less from crucial missing data or from variability in the nature of the evidence. Areas such as religion and belief were understood to

be less tightly tied to materiality, and thus archaeologists were likely to lack crucial pieces of evidence to support explanation, or they might recover material that could be explained in multiple ways and have no basis to choose between explanations. Hawkes explicitly argued that understanding areas like religion and symbolism would be most feasible where written texts were available.

In contrast, in initial programmatic statements for the processual archaeology of the early 1960s, Lewis Binford (1962) argued that all aspects of culture, including ritual, were open to scientific archaeological analysis if questions were properly framed. Binford argued that objects could be identified whose primary use was to convey symbolic meanings as part of the reproduction of society. These Binford labeled sociotechnic and ideotechnic. An example would be an axe or knife made of soft metal like copper. Not useful as an actual weapon, this object would not qualify to be identified as technomic (used for pragmatic purposes, as a knife made out of hard material capable of being used to cut something). As a sociotechnic object, it might have served social purposes, such as marking rank or status. As an ideotechnic object, it might have been a pure symbol of mental concepts, such as those that formed part of religions.

Employing a processual framework, Robert Drennan (1983) developed an explicit set of expectations for how archaeologists could identify the material evidence of ritual. Drennan based his understanding of religion on the work of social anthropologist Roy Rappaport (1979). For Rappaport (1979: pp. 117–121, 207–211, 231–234), religion was a set of widely shared ideas about the nature of the world and the place of people within it. Defined in this way, religion would, as Hawkes (1954) argued, be beyond archaeological investigation, unless the archaeologist had access to written texts. What made Rappaport's approach useful for archaeologists was his argument that religion was enacted in ritual. Ritual contrasted with belief, which was interior, private, and inaccessible (Rappaport, 1979: pp. 194–195). The effect of ritual was to combine "the most abstract and distant of conceptions" with "the most immediate and substantial of experiences," transforming "the dubious, the arbitrary, and the conventional into the correct, the necessary, and the natural" (Rappaport, 1979: p. 217). Rituals were "stylized, stereotyped and repetitive"; they required "the proper persons, occasion, place, and time" (Rappaport, 1979: pp. 175–176). As a consequence, rituals left material traces that archaeologists might recover.

Following Rappaport, Drennan defined rituals as sequences of repeated action directed at intervening in relations between humans and supernatural forces or beings. Among the key features he and other processual archaeologists used to attempt to objectively identify remains stemming from ritual were associations between otherwise rare items, and the recovery of such rare items from public spaces. For example, unusual elements of animal skeletons found near open public spaces could be interpreted as part of costumes worn during ritual performances. The approach Drennan employed assumed a separation between an everyday sphere of activities and a separate sphere, the domain of ritual, detectable by distinctive location and unusual artifacts.

Processual approaches required external bodies of information for the formulation of models of ritual and symbolic systems, but unlike the limitation to historical situations where beliefs were recorded in texts, proposed by Hawkes (1954), processual archaeologists drew on analogies among different societies to construct models for less well-documented societies. Often this involved using societies observed by ethnographers to propose models for archaeological societies. Specific ethnographic analogy, commonly known as the direct historic approach, was based on the study of living societies believed to be descended from the archaeological population that created a specific site. For specific analogies to work, there had to be an assumption that little or no change had occurred over time. General analogies were based on comparative ethnographic samples such as those contained in the Human Relations Area Files (http://www.yale.edu/hraf/). The power of explanation rested on the strength of arguments linking the analogies to the test case, requiring extremely broad uniformitarian generalization. The level of generalization required made explanations of ritual and symbolism extremely vague, and tended to substitute the operations of superorganic entities for individual actions (Wylie, 1985).

The most systematic processual definitions of the conditions needed to identify spaces and objects as evidence for ritual have been provided by British archaeologist Colin Renfrew (1985, 1994). In his view, religion is unobservable, because it concerns belief in metaphysical beings. Religion could in theory affect any part of human activity, and thus could structure any part of the material world. Ritual, in contrast, was the practice of specific actions motivated by religious belief. Renfrew (1985) provided what he characterized as a framework to infer religion, which he later modified (Renfrew, 1994), that has remained influential. In his original formulation, intended to help him argue that certain sites were cult centers, he called for attention to those features of the archaeological record that allowed a 'focusing of attention' by ritual participants. Understanding ritual as situated at a boundary zone between the everyday world and a supernatural world, Renfrew's model directed archaeological attention to certain kinds of spaces, of which hill-top shrines were an example. Religious rituals involved making deities present, through actions such as offerings, which would produce identifiable material residues. These linking arguments allowed Renfrew to propose that certain locations, features, and objects might be expected in places where ritual was carried out. These included the practice of ritual in special geographic settings or special built environments; the use of objects to assist in focusing, including altars, ritual vessels, lamps, or the like; the production of images of deities or of animals symbolically related to supernatural beings; and ritual actions such as music, dance, and other bodily practices that might leave material traces.

Renfrew (1994) revisited his original formulation in a more general discussion of the possibility of a cognitive processual approach to religion as part of an archaeology of mind. This involved defining religion as "the role of symbols in coping with the unknown and the supernatural" (Renfrew, 1994: 47). He argued that archaeologists were most likely to identify religious activities when they took place in specialized locations, even though there might be religious practices

'embedded' in everyday life. Renfrew suggested that iconographic representation would likely be a useful route to pursue religious ideas, such as the separation of a soul from a body after death. Some of these iconographically represented ideas, he suggested, might be common if not universal aspects of human religions.

While Renfrew's framework has been influential, it is not without critics. Timothy Insoll (2004: pp. 92–96) criticizes Renfrew's approach for leaving out the numinous, an aspect of individual experience, and for projecting a universal view of religion that implicitly is based on Christian practices that assume separation of the sacred and religious from the everyday and secular. These concerns have become more important in contemporary archaeology of religion, including the study of world religions and the neuropsychology of individual religious experience.

Ritual as Practice and Structured Deposition

While the processual approaches reviewed above are influential, they were ultimately critiqued for failure to provide satisfactory accounts of human agency. Following such postprocessual critiques (Hodder, 1982b), archaeologists working on questions of ritual rapidly adopted new models of religion. Especially influential was the perspective developed by Catherine Bell (1992) who proposed that in place of ritual, analysts should examine ritualization: "a way of acting that is designed and orchestrated to distinguish and privilege that which is being done in comparison to other, usually more quotidian, activities" (Bell, 1992: p. 74). Rather than being a question of identifying sites used for ritual, or objects used in ritual, this definition offered the potential to examine what people were doing that marked some actions as different from others.

In this vein, archaeologist Richard Bradley (2003) argued that treating ritual as action rather than as a series of symbolic statements "makes it possible to consider the contexts in which particular rituals are created and performed, and the consequences of such actions, whether they have been intended or not" (Bradley, 2003: p. 12). Bradley based his analyses on the archaeological concept of 'structured deposition' (Richards and Thomas, 1984): a means to understand archaeological deposits as products of more or less intentional activity, including the kind of stylized practices Bell would call 'ritualized.' Bradley (2003: p. 8) argued that the association of otherwise unremarkable objects in structured deposits in some British Neolithic sites was "governed by a number of conventions" suggesting "a degree of formality" that is "a defining feature of ritual."

Independently, archaeologist William Walker (1998) developed a concept parallel to that of structured deposition from a behavioral approach, rather than one grounded in practice theory. Walker rejected the idea that archaeologists could identify specific objects as evidence of ritual. Instead, he emphasized contextual clues indicating that objects were used in ritualized ways. Walker emphasized extreme destruction or fragmentation as a key sign of the ritualized disposal of things used in ritualized practices.

The convergence of these two analyses, one rooted in consideration of intentional human agency, the other explicitly behavioral and thus avoiding any presumptions about intentions, has added weight to the use of contextual patterns in deposition as evidence of ritualization by archaeologists from a wide spectrum of approaches.

The Material Basis for an Archaeology of Ritual and Symbolism

Despite the shifts in emphasis over time, the specific material bases employed in archaeology of ritual have remained fairly stable. Offerings or caches, burials, particular spatial locales, and visual images have consistently provided the subject matter for analyses of ritual.

Caches and Offerings

Caches, hoards, or offering deposits figure as primary evidence of ritual in several regional traditions in archaeology, particularly North America, Central America, the eastern Mediterranean, and Neolithic Europe (Bradley, 1991). Interpretations of caches vary from purely materialistic to ideational. Some analysts stress the economic effect of the withdrawal from circulation of a large quantity of specialized goods at one time. Others propose structural-symbolic interpretations in which materials employed worked to create specific associations between ideas about the supernatural world and the locale of the offering, consecrated by the deposit. Explanations of both kinds have been offered for the same deposits, and indeed, they are not mutually exclusive, since a ritual action can have both pragmatic and symbolic effects.

Burials

Mortuary analysis, the study of sites and artifacts related to human burial, has occupied a central place in the archaeology of ritual. Studies conducted under normative assumptions described burial customs, including the laying out of the body according to symbolic beliefs (such as the eastward orientation of the head, toward the rising sun). The removal of skeletal elements from burials and the practice of secondary burial have been seen as unambiguous evidence of ritual practice. The deliberate burial of animals has generally also been regarded as evidence of ritual activity.

Processual archaeology directed attention to the generation of covering laws or assumptions that could link the forms of burials, and particularly, diversity among them, to social differences. Burials were seen as reflecting the social identity of the deceased. They operated as mechanisms to assert claims for territory. Postprocessual archaeologists viewed burial assemblages as the material media of ancient rituals, and demonstrated that mortuary remains can mask social relations as easily as they can reflect them (Hodder, 1982b).

Temples and 'Sacred Landscapes'

The identification of special sites for ritual, through spatial segregation, specific construction, or a combination thereof, is also a consistent aspect of archaeology of ritual. While buildings called temples today may sometimes be unambiguously identified through written documents, such as ancient Egyptian and Maya inscriptions, in other cases the identification of temples is solely made based on inferences of the analyst. In keeping with other approaches that examine the active role of

humans in ritual, some archaeologists have explored how different spatial settings structure ritual action (Moore, 1996).

Spaces that can be viewed as nonordinary by nature are sometimes treated as effectively unproblematic locales for an archaeology of ritual. Caves and natural springs are prominent foci for some definitions of such sacred geographies. In contrast, the investigation of entire landscapes, such as those of megalithic Europe, emphasizes the social marking of space through ritual action, denying an attempt to separate categorically sacred landscape features from the pragmatic experiences of human agents (Richards, 1996).

Visual Images

Visual images recovered archaeologically have been a staple in reconstructing ritual. They have been approached in two complementary ways. On one hand, researchers have argued that images or scenes represented mythologies or beliefs about the supernatural. Some have been identified as models for ritual enactment. For example, elaborately dressed individuals buried at the coastal Peruvian Sipan site have been identified with the clearly nonhuman figures depicted in presumably mythological scenes on pots made and used within the Moche kingdom (Chapdelaine, 2011). The implication that such acts as ritual decapitation and mountaintop sacrifice actually took place within ancient Peruvian society has been supported by the recovery of caches of skulls and of frozen bodies on the high Andes. Here, the pottery scenes are viewed as imagery of mythology, and the burials and sacrificial deposits as re-enactments of these mythological scenes.

In other cases, representations have been interpreted as recording ritual practices, but not their mythological charters, usually because of the embedding of ritual in other aspects of social life. For example, Classic Maya monuments have been identified as showing members of the ruling class engaged in ritual bloodletting and the sacrificial burning of paper and resin, ritual actions that simultaneously served to validate sociopolitical hierarchies (Schele and Miller, 1986).

Current Issues

The archaeology of ritual began with an emphasis on the study of societies where texts governing practice were either not in widespread use, or were unavailable for analysis. This led effectively to an archaeology of ritual unrelated to questions about religious belief. Current debate in the field, based especially on new attention to religious practice in world religions, traditions with broadly shared bodies of theological texts, has criticized the primacy of studies of ritual, and the ways that ritual and religion have been linked by archaeologists.

Thus Fogelin (2007: p. 66) suggests that "archaeologists often assume that ritual is a form of human action that leaves material traces, whereas religion is a more abstract symbolic system consisting of beliefs, myths, and doctrines." He suggests that archaeologists differ on whether they see religion or ritual as primary. Taking religion (belief) as primary leads to viewing the field of actions through which people engage with the world as a play of symbols. Approaching the same body of activities as pragmatic action leads to an emphasis on tracing the sequence of actions and their repetition as the historical reproduction of practices, and the sequential process of semiosis.

Many contemporary archaeologists continue to pursue the study of ritual, understood as the more materially evident aspect of belief-inspired action (e.g., Kyriakidis, 2007). But at the same time, a large body of archaeological work on world religions has developed, for the most part avoiding definitional questions, and stressing particularities over generalization (Insoll, 2001). Examples include studies of the religiosity of Christian nuns (Gilchrist, 1994); the effects of Quaker belief on the material world in which Quakers lived (Chenoweth, 2009); and investigations of religions like Buddhism and Islam where, unlike in Christian practice, a separation of everyday and spiritual realms should not be expected and cannot be used as a methodological approach (Insoll, 2001).

Insoll (2004: p. 6) argues that archaeologists using ritual as a methodological focus are trapped by structures specific to one religion, Christianity, with its division of experience between religious and mundane. He insists that the object of study for archaeologists must be religion, not ritual. However, he declines to give a precise definition of 'religion,' arguing that "in many respects it is indefinable, being concerned with thoughts, beliefs, actions and material … religion also includes the intangible, the irrational, and the indefinable" (Insoll, 2004: p. 7). Insoll identifies the visibility of religion, the role of myth, ritual, temporality, its relation to identity, 'belief/emotion/experience,' and the status of 'the numinous/the holy' as among the questions that any archaeological analysis of religion needs to address (Insoll, 2004: pp. 148–150).

One way other archaeologists have directly addressed the experiential dimension of religion is by relying on universal neurobiological responses to stimuli that are materially evident, or can be assumed to have been present. The most developed examples of this approach concern experiences of altered states (such as trances), especially associated with models of shamanic ritual practice (Lewis-Williams, 2002). Trance, induced through a variety of means (including ingestion of drugs, music and dancing, and even specific bodily stances) has been found to produce the same sequence of effects on the human body. These effects include visualization of geometric shapes such as wavy lines, called entoptic phenomena, which are interpreted by the brain as intelligible forms, often combining human and animal features. The person ultimately experiences sensations of physical movement, often described as flying. Lewis-Williams (2002) and others argue that various forms of rock art, including spirals and animal-human hybrids, are related to these neurobiological experiences. The argument that these experiences are grounded in universal biological capacities provides a means for these archaeologists to argue that ancient subjects were experiencing particular sensations that might be considered numinous.

As archaeologists have turned their attention to religious experience, some have begun to engage with specialists in religious studies. Recent interdisciplinary collaborations have directly addressed such questions as belief in spiritual domains and the emergence of human representations (Renfrew and Morley, 2007). One outcome of these interdisciplinary engagements is the identification of a concern with 'modes of

religiosity' in place of either religion itself, or ritual practice. In a joint discussion of the evidence from Neolithic Çatalhöyük, for example, Ian Hodder and Harvey Whitehouse (2010) discuss how the particular evidence at the site for a historical transition from highly marked, but less frequent, ritual settings, to more frequent, structured, and perhaps narrative religious practices might be related to Whitehouse's concepts of imagistic and doctrinal 'modes of religiosity.' Imagistic modes are understood to be more idiosyncratic, and emotionally charged, while doctrinal modes are abstracted and generalized. Whitehouse's discussion makes it possible to recognize that most archaeology of ritual involves doctrinal modes of religiosity, and leaves out the more personal but perhaps sometimes more compelling experiences he describes as imagistic.

Symbolism, ritual, and religion are clearly subject to study through material traces. Semiotic analyses may play a stronger role in the future in encouraging understanding of how religious meaning is produced (Schoenfelder, 2011). Personal experience, religiosity, and the ways objects and deposits are enlisted in religious practices will likely continue to be focal as archaeologists continue to explore ritual and religion from the perspective of the individual human agent and institutional religion.

Abstract

Joan Robinson was born into an upper middle class English family with a tradition of dissent. She was educated at St. Paul's Girls' School and Girton College Cambridge where she read economics in the 1920s. After 2 years in India she made her home in Cambridge as a member of the Faculty of Economics and Politics from 1934 on. She made major contributions in virtually all branches of economic theory, becoming progressively more critical of mainstream neoclassical economics as the years wore on. Her approach increasingly derived from the Classicals, Marx, Kalecki, and Keynes of *The General Theory*. She was an inspired teacher. She died in August 1983.

Joan Robinson was born on 31 October 1903, in Camberley, Surrey, into an upper middle-class English family characterized by vigorous dissent and independence of mind. Her great-grandfather was F. D. Maurice, the Christian Socialist who lost his Chair of Theology at King's College, London, on a point of principle; her father was Major General Sir Frederick Maurice, the victim of the infamous Maurice debate in 1918 and subsequently Principal of what is now Queen Mary College in the University of London. Her mother was Helen Margaret Marsh, the daughter of Frederick Howard Marsh, Professor of Surgery and Master of Downing at Cambridge. Joan Robinson was born into a milieu of controversy. She was educated at St. Paul's Girls' School in London, where she read history, and from 1922 to 1925 at Girton College, Cambridge, where she was Gilchrist Scholar. There she read for the Economies Tripos, searching for rational argument and hoping to understand poverty and its cures. She graduated in 1925 with second-class honours ('a great disappointment' – her words) although it was not until 1948, when women were given full membership of the university, that she was admitted to the degree. In 1926, she married Austin Robinson, the Cambridge economist, and the couple sailed for India for what was to become the first of many visits. They stayed for over 2 years and returned to Cambridge in 1929, making it their intellectual and domestic base for the rest of their lives. They had two daughters and five grandchildren. Joan joined the Cambridge Faculty of Economics and Politics as a Faculty Assistant Lecturer in 1934, becoming part of an outstanding group of scholars in Maynard Keynes, A. C. Pigou, Dennis Robertson, Austin Robinson, Maurice Dobb, Richard Kahn, Gerald Shove, and Piero Sraffa. She became a University Lecturer in 1937, Reader in 1949, and Professor in 1965. She was elected to a Professorial Fellowship at Newnham and made Honorary Fellow of Girton in 1965, and Honorary Fellow of Newnham in 1971; she was the first woman to be made an Honorary Fellow of King's (in 1979). From 1958 to 1971 she was an FBA. She 'retired' from her Chair in 1971, remaining as active as ever in Cambridge and abroad, until her death in Cambridge on 3 August 1983.

Early in her career Joan Robinson set out her views on methodology for economics, (Robinson 1932a, Harcourt 1990a). Her procedure was to identify and make explicit her assumptions and to develop a 'box of tools' for understanding and exploring the analytical object, to construct a logically sound analysis of the processes concerned: these successive stages she saw as independent of each other. Extending these views, she suggested (1937b, pp. 99–102) that controversy could result from lack of understanding, lack of knowledge, errors of logic, from working from different assumptions but, most commonly in economics, from differences in (political) objectives: the goals of a theory could direct its analysis as well as its policy conclusions. Throughout her life she argued that economics is not neutral, it is always ideologically driven. Nevertheless she believed that it was possible to develop pure analysis independently of dispute.

Her early contributions to economic theory were mainly in the realm of value theory (microeconomics, as it is called now) and *The Economics of Imperfect Competition* (1933), her first book, generously acknowledged her debts to Marshall (via Pigou), Kahn, Austin Robinson, Shove, and Sraffa. It was a controversial and much celebrated success, revealing her great clarity of thought and exceptional analytical powers. It was her interpretation, within a Marshallian context, of several contemporary theoretical issues. In particular, it was a response to the heretical claims about decreasing costs and increasing returns being made in the *Economic Journal*, especially Sraffa (1926), Symposium (see Robertson et al., 1930), and including Robinson (1932b). Robinson replaced an analytical basis in Marshall's free competition with one in imperfect competition, where free competition became a special case. She also moved the focus from Marshall's long period to a short period. Within that context the book also presented new concerns. On the basis of the downward sloping demand curve for each firm, Robinson introduced the marginal revenue curve as an integral analytical construct. She showed how the response of relative factor shares to a change in demand depended on whether you used her partial analysis of the elasticity of substitution or Hicks', aggregate. She reconceived Marshall's 'representative' firm as an 'equilibrium' firm where each such firm faced a less than infinitely elastic demand curve for its product in a monopolistic market. What then became 'the industry' in such a market? And was the simple profit-maximizing rationale too reductionist to depict the firm? How was a monopolist to be identified theoretically?

Or a duopolist? How indeed was imperfect competition definable?

The Economics of Imperfect Competition provoked; each stage of the theoretical process, even her geometrical method, incited reaction. More controversial than her analysis were its implications for policy. She represented perfect competition theory as demonstrating that the economy left alone would generate the optimal outcomes: it suggested a political philosophy of *laissez faire*. Imperfect competition showed that left alone the economy could become stuck at a position of unemployed capacity and labour and indeed, at that time, this was the case. The debates on the elasticity of substitution further illustrated what the emerging critique of perfect competition theory could mean for the status quo. The issues raised in this book were to fill the journals for decades to come. She herself came to reject its analyses (postwar) as a 'shameless fudge.'

Robinson's interests were not confined to microeconomics. During this time she was a member of a group of economists who met to discuss John Maynard Keynes's *Treatise on Money* (1930) and his emerging new theory. His ideas appealed to her, they represented a break from the orthodox and they were focused on the pressing problem of the persistence of high levels of unemployment. As a member of the Circus, with Meade, Kahn, Austin Robinson, and Sraffa, Robinson contributed to the critical scrutiny of drafts of Keynes's *The General Theory* (1936). A formidable group, but they were persuaded by the dissenting view of the behaviour of investment and of saving in Keynes's new theory of output and employment. Immediately following the book's publication, she wrote to develop its themes and analysis. *Essays in the Theory of Employment* (1937a) and the popular *Introduction to the Theory of Employment* (1937b) were both published in the year following *The General Theory* (and in the same year that her second daughter was born). She sent Keynes drafts of the two books as well as the proofs, and the related correspondence reveals his respect for Robinson in her role as his interpreter. *Introduction* is still one of the best guides to *The General Theory*.

During the interwar years, Michal Kalecki had a major impact on Robinson's thinking. His preemptive version of the theory of effective demand, which interwove imperfect competition with a macro-economic theory of distribution, was based on Karl Marx's schema of reproduction and his analysis of the realization crisis. She integrated his double-sided relation between investment and profits and his short-period theory of income distribution to develop her theory of employment and output. Kalecki provided a structural base to Robinson's theoretical explorations and extensions of Keynesianism and later of growth. During the war Robinson wrote *An Essay on Marxian Economics* (1942). Her interest was partly attributable to Kalecki's and Sraffa's Marxist-based work, and partly to the structure of society portrayed by, and fundamental to, such classical and Marxist analysis; her continued dissatisfaction with orthodox theory was also reflected in her essay which compared Marxian with mainstream ideas.

Robinson's interpretation of Marx again illustrates her approach to constructing theory. Responses to her book were to her methodology, as well as to her critical remarks about both Marxian and neoclassical economics. She extracted from Marx's writing the circuits of deductive logic with their attendant assumptions and political implications. The methodology of her censorship was not so inclusive as to embrace Marx's theory of history and of the processes of change. Yet it was these elements – the centrality of historical analysis to Marx's method and of class to understanding effective demand – that attracted Robinson to Marx's writings. The pervasive implications of time and history underlay her vision of capitalism and informed all of her subsequent economic research even though she ultimately was to abandon the classical method. Her book was a challenge to her colleagues to read and learn from Marx, if selectively and from a Keynesian perspective. It remains a useful introduction to Marxist economics.

In the early postwar years Robinson became committed to developing a dynamic analysis of capitalism. Inspired by Harrod's (1939, 1948) studies of long-period growth, *The Rate of Interest and Other Essays* (1952) was a collection in preparation for this project, in particular. The generalization of *The General Theory* attempted to extend Keynes into the long period. This essay was an interpretation of Keynes in terms of the Marshallian short period, characterized by uncertainty, incompatible decisions and unrealizable expectations, by a new definition of equilibrium. The elements of Robinson's growth theory were coming together in a non-neoclassical and long-period framework.

Integral with Robinson's exploration of long-period accumulation was an increasing dissatisfaction with the conceptual and logical foundations of neoclassical theory and its method, for which she became most well known, if not best understood. She prefaced her constructive contributions to dynamic theory with the critique of the neoclassical production function, Robinson (1953–54). This article fired a debate that continued for more than two decades. The implications of these exchanges were for the legitimacy of the very concept of capital and hence of the aggregate production function, fundamental to neoclassical theory. In particular, Robinson targeted its distribution analysis and its corollary, value theory. Ultimately, she criticized its method, that "the neo-neoclassics still refuse to understand the difference between a comparison of timeless equilibrium positions and the effects to be expected from a change taking place at a particular moment" (1978a, p. xix). That particular moment was characterized by its own inherited structure of decisions, expectations, and uncertainties. She rejected the neoclassical method of long-period equilibrium as a point toward which the actual economy is moving; the implied stationarity of that theory meant that the movement toward it, and the rest point were logical, not historical. Her own account would not be in equilibrium terms but would take into account the actual features of the economy, the existence of uncertainty, and disappointed expectations. Her understanding of capitalism was based on classes and relations of conflict, while the neoclassicals begin with technical factors and harmonious distributive shares. What she wanted to put in the place of neoclassical theory was not a rival complete theory, which she considered would be only another 'box of tricks,' but an approach that started from institutions, history, and the 'rules of the game' (Harcourt, 1990b). Robinson's optimism about the power of economic debate was continually frustrated, yet she determinedly defended what seemed to her to be right and

just arguments. Her conservative colleagues, she felt, treated new ideas 'like heresies.'

The Accumulation of Capital (1956) continued the 'generalization' within a classical framework. The questions she set out to explore were: what are the conditions for cumulative long-term growth of income and capital (Golden Age) and what is the outcome of this process in terms of growth of gross and net output and the distribution of income between wages and profits, given a certain evolution through time of the labor force and technology? Inspired by Harrod's 'fruitful provocation,' *The Accumulation of Capital* brought together Marx's historicism, Harrod's economic dynamics, and Wicksell's capital theory. True to her methodology, she started out by presenting her most basic model and then devoted the rest of this remarkable book to relaxing the 'most severely simple' assumptions and tracing out the implications. 'The whole argument,' she proposed, "is set out ... as an analytical construction, with the minimum of controversy" (1956, p. x). In contrast to the mathematical style endemic to American economics, Robinson wrote her entire work of pure theory in literary form. It was a difficult book to assimilate and several years later she followed it up with a hands-on guide. *Exercises in Economic Analysis* (1960) fills in the gaps, clarifies obscurities, and extends the arguments from *The Accumulation of Capital*. Its object, Robinson stated, was 'to sort out questions' (1960, p. xx). It offers readers an opportunity to formulate for themselves the analytical examples she derives in *The Accumulation of Capital*. This book (1960) was immediately followed by *Essays in the Theory of Economic Growth* (1962) which presents a retrospective introduction for the 'too terse' earlier (1956) book. Although there was a hint of re-switching in Robinson (1953–54) as well as in *The Accumulation of Capital*, Robinson dismissed the phenomenon at the time and saw it as a distraction from the main methodological point of her critique of neoclassical capital.

Dissatisfied with her quest for a long-period theory of growth, Robinson looked more to Kalecki's theory of cycles as a depiction of capitalism. She was a pioneer in the development of what was to become post-Keynesian theory, its bases in Sraffa's interpretation of Ricardo and in Kalecki's interpretation of the theory of employment. To this she brought 'a general framework of long- and short-period analysis which will enable us to bring the insights of Marx, Keynes, and Kalecki into coherent form and apply them to the contemporary scene' (1978b, pp. 1, 18). Within this framework, post-Keynesian theory offered a 'method of analysis which takes account of the difference between the future and the past' (1978b, p. 12). Here was a broad conceptual structure that brought together Robinson's major theoretical concerns. From this analysis, post-Keynesian theory is evolving in several, not always compatible, directions, establishing its authority in the body of economic theory.

Robinson was a charismatic teacher; she inspired successive generations of students to develop their own ideas from her methods of analysis and brilliant insights, to think critically and for themselves. She spent many years demonstrating that 'mainstream teaching has been inculcating defective methodology'; she wanted to provide a logically sound, historically based dynamic approach to first-year economic analysis. *An Introduction to Modern Economics* (1973) with John Eatwell was a response to the 'fashionable textbooks [of] mainstream' economics. It presented a history of thought, a classical-cum-Kaleckian/post-Keynesian analysis. It was an ambitious, presumptuous book, at once a critique of neoclassical theory, and a terse introduction to the alternative. Robinson overestimated the intuitive powers of her audience and it proved too difficult for beginners; it remains a challenge for more advanced students.

Throughout her life Robinson pursued an active interest in the Third World, in India and China in particular, and in the Soviet Union. Her initial writing on development was based on the growth models developed in *The Accumulation of Capital*. Kalecki influenced this book. Development, she argued, should proceed by appropriate land reform and industrialization in both agriculture and manufacture, mindful of the balance of payments constraint and a minimum real wage or its equivalent. Socialist development, she continued, could mobilize savings and enable the state to organize the investment of the surplus, so achieving faster if not more efficient accumulation and growth than under capitalism; socialism, furthermore, led to a more equitable distribution of income (although the standard of living she saw as a political decision). She was less enthusiastic about the Soviet-style socialism of Eastern Europe than she was about China. Her mission to eradicate poverty and to meet basic needs always guided her judgements. She leaves a body of work; some reprinted in her *Collected Economic Papers* as well as Robinson (1979), on development planning and socialism that is relevant and provocative.

Joan Robinson depicted her work as an agenda for discussion as well as formulating the questions. Yet she has left an important legacy in her substantial literary output. She wrote for colleagues, students, and for the general, interested reader. As well as her many books, there is a stream of challenging evaluative essays written through the 50 years of her career. Her writing includes a theoretically rigorous critique of neoclassical economics that as yet goes unanswered; the questions she has raised present a formidable program for further research. She leaves an exacting methodology, a theoretical structure, and significant analytical details of a new, unified system of political economy.

Robustness

Stephan Morgenthaler, Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Published by Elsevier Ltd.

Abstract

Robustness is a crucial quality indicator of any procedure used in a data analysis. The most basic attribute of robustness of such a procedure is its sensitivity (or influence function). The sensitivity assesses the effect of an additional observation on the results of the data analysis, if that observation takes an arbitrary fictitious value u. If we estimate something with an estimator that has bounded sensitivity, the results are more trustworthy. If the estimator has unbounded sensitivity, we cannot be confident because a single observation may have determined some of the conclusions.

The breakdown point of a statistical method is the minimal fraction of the observations that, when manipulated, have the potential to render a data analysis meaningless. This is an example of a global attribute of robustness. It goes beyond sensitivity in an important respect, because it assesses the behavior of a procedure if a sizable proportion of the database were arbitrary and fictitious, not only one observation.

Contaminated distributions such as $(1-\varepsilon)\Phi(\gamma)+\varepsilon H(\gamma)$ are useful in modeling such fictitious and arbitrary values. With a (large) probability of $(1-\varepsilon)$, this mixture distribution results in an observation drawn from a normal distribution Φ, whereas with a (small) probability ε the contaminating distribution H generates the observation. Such models can provide useful checks for choosing estimators. While the arithmetic mean is the correct choice of estimator and if the observations have random errors with $\varepsilon=0$, it turns out that even for tiny positive ε this is no longer true. The arithmetic mean's place as the best choice is then taken by the Huber estimator.

We all routinely use the arithmetic mean for estimating the expectation of a random variable based on a sequence of observations. It is indeed the best way to summarize observations, if they are distributed according to the bell-shaped normal density. Tiny deviations of the actual distribution from the normal ideal, however, can turn the arithmetic mean into a horribly bad estimator even though the observations come from a density that is very nearly a normal density. This illustrates what is meant by robustness of an estimator. The estimator's properties must be stable (or robust) under deviations from the postulated stochastic model. What I had in mind when modeling the data is different from the actual stochastic properties of the observed data, even if the model is a very good one. These differences should not be allowed to affect the performance of the procedure used in the data analysis.

The robustness of estimators or other procedure may also be defined without reference to a model. The arithmetic mean of the three observations (14.0%, 13.7%, 26.3%), for example, is equal to 18.0%. The lack of stability of this estimated average percentage is visible through the large effect of the single observation 26.3% on the estimated value.

Implicit and explicit assumptions of a data analysis based on a stochastic model are of various types. In a generalized linear model, for example, they include the link function, which determines the scale on which the relationship between the response and the explanatory variables (or covariates) is of the form of a linear combination of the covariates. Another assumption concerns the cumulative distribution for the response, which determines certain aspects of the inherent randomness of the data, such as the form of the relationship between the standard deviation and the expectation of the response variable or the rate of growth of the extreme $(1-\alpha)$ quantile of the response variable as α tends to zero. The best-known phenomenon observed in data concerns the so-called outliers. This is a term used in describing various incidents in a database. It may refer to gross errors in observations due to faulty transcription, mistakes in the manipulation of a measurement instrument, errors in the preparation of a particular experiment, confusion as to which experiment should have been performed, or some other such mistake. The frequency of such gross errors is much higher than one would expect at first thought, even in data obtained through a carefully designed experiment and of course probably even more so in observational studies. It is also possible that an atypical observation is an actual measurement in situations where the range of the errors of the instrument is simply much larger than we expected. The term outlier may also refer to a situation, in which a sizable proportion of the data seems to behave differently from the rest. In a linear regression, for example, it is sometimes observed that any one regression surface fits only part of the data. This occurs with observational studies or designed experiments, if important covariates are missing and the data cannot be separated into more homogeneous pieces based on the available information.

Of course, the data can be used to check assumptions and it is certainly a good statistical practice to do so. To check the details of a model, however, requires huge amounts of data and it is misleading to suggest that diagnostic checking of model assumptions can solve the robustness problem. Good practice in statistics requires the use of methods that do not suffer the drawbacks of the arithmetic mean of loosing performance under tiny violations of the idealistic assumptions. This is especially true in routine and less thoroughly scrutinized applications of statistical methodology. Robust methods retain very good performance, while being less sensitive to assumptions.

In the future, data analysis will increasingly be applied to very large databases composed of data from multiple sources of uneven quality. In such applications, the call for robust procedures will grow louder.

Robustness seems similar to nonparametric or, more precisely, distribution-free statistics. This is a superficial and even wrong view. Converting data to ranks, for example, in order to liberate the statistical analysis from distributional assumptions, does not give particularly good protection from the deleterious effects of gross errors.

Indicators of Robustness

Sensitivity Functions

Let $T(y_1, \ldots, y_n)$ be a statistic based on the observations $(y_1, \ldots, y_n)$ and suppose that T is estimating some unknown quantity. The sensitivity function is a simple idea leading to a better understanding of the behavior of the statistic. The question being asked is: how would the estimator have come out, if the data had not been exactly the ones I observed? To answer it, one considers the sensitivity function,

$$\mathrm{SC}(u) = (n+1)(T(u, y_1, \ldots, y_n) - T(y_1, \ldots, y_n))$$

which is the change in the estimate induced by an additional fictitious observation u. The multiplier $(n+1)$ in this formula provides a natural scaling of the size of the change. Inversely, it follows from this definition that

$$T(u, y_1, \ldots, y_n) = T(y_1, \ldots, y_n) + \frac{1}{n+1}\mathrm{SC}(u)$$

which is a formula for updating an estimator is a new observation that becomes available. Examples, for the arithmetic mean $T(y_1, \ldots, y_n) = \bar{y} = (y_1 + \cdots + y_n)/n$ one finds

$$\mathrm{SC}(u) = (n+1)\left(\frac{u + y_1 + \cdots + y_n}{n+1} - \frac{y_1 + \cdots + y_n}{n}\right) = u - \bar{y}$$

This sensitivity function shows that the sensitivity of the arithmetic mean equals the distance of the additional observation u from the average of the observed data. If all values of u are considered, the sensitivity is unbounded.

For the trimmed mean, $T(y_1, \ldots, y_n) = (y_{(2)} + \cdots + y_{(n-1)})/(n-2)$, obtained by deleting the largest $(y_{(n)})$ and the smallest $(y_{(1)})$ observations before taking the arithmetic mean, the sensitivity depends on the position of the additional observation u with regard to the initial data. If u is between $y_{(1)}$ and $y_{(n)}$, it will not be trimmed from the sample and $\mathrm{SC}(u) = (n+1)((y_{(2)} + \cdots + y_{(n-1)} + u)/(n-1) - (y_{(2)} + \cdots + y_{(n-1)})/(n-2)) = (n+1)(u - T(y_1, \ldots, y_n))/(n-1)$. If on the other hand, u is larger than $y_{(n)}$, then u will be trimmed and the sensitivity no longer depends on u and is equal to $\mathrm{SC}(y) = (n+1)((y_{(2)} + \cdots + y_{(n)})/(n-1) - (y_{(2)} + \cdots + y_{(n-1)})/(n-2)) = (n+1)(y_{(n)} - T(y_1, \ldots, y_n))/(n-1)$. An analogous formula holds when u is smaller than $y_{(1)}$. Merely by trimming the extremes from the observations before computing the arithmetic mean, we can thus bound the sensitivity, and in view of the desirability of using robust estimators, the trimmed mean is much better than the arithmetic mean. But we cannot stop here. The trimmed mean is much better, but is it good enough?

As a third example, we now consider the least-squares estimator of a slope (or a regression coefficient) in the model $y = \alpha + \beta x +$ random error. In this case, we observe the couples of a covariate and a response, $(x_1, y_1), \ldots, (x_n, y_n)$, and we add a fictitious observation at (u, v). Recall that the least-squares estimate of the slope β is $\widehat{\beta} = T(y_1, \ldots, y_n) = \sum_{i=1}^{n} y_i(x_i - \bar{x})/\sum_{i=1}^{n}(x_i - \bar{x})^2$, which can be simplified by centering the covariate $(\bar{x} = 0)$. Assuming a centered covariate, the estimate of α is $\widehat{\alpha} = \bar{y}$. Computing the sensitivity $\mathrm{SC}(u, v)$ caused by an additional fictitious observation is complicated and we leave it to the interested readers as an exercise. The result is approximately proportional to a product of two terms, the residual $(v - \widehat{\alpha} - \widehat{\beta}u)$ (residual with respect to the regression line based on the initial data) and a term that is essentially linear in u. As in the other two cases, this is a revealing formula. It makes it clear that the least-squares regression coefficients are sensitive to the outlyingness of the additional observation with regard to the regression line of the initial data as measured by the residual. But, this effect is multiplied by the position u, the further u is placed from the mean of the initial covariates, the more the effect of outlyingness is leveraged. Adding an outlying observation at or beyond the edge of the initial covariate values is much worse than adding it centrally.

In practice, the sensitivity function can easily be computed numerically for any given estimator and underlying data set and one can thus construct the plot of $\mathrm{SC}(u)$ versus u, which in many cases will serve as a good basis for judging the sensitivity robustness of the estimator. From such a plot, one can deduce several indicators, the simplest one being the maximal sensitivity

$$g^* = \sup_y |\mathrm{SC}(y)|$$

where $|\mathrm{SC}|$ denotes the absolute value of SC. In the above examples, the maximal sensitivity is equal to ∞ for the mean and the least-squares estimate of the regression coefficient – the first and the third example. It is finite for the trimmed mean. An estimator with infinite maximal sensitivity is necessarily nonresistant in the sense that a single wild observation that behaves differently from the rest can destroy the estimate and lead to arbitrary conclusions based on a single observation, conclusions not supported by the remainder of the data.

Influence Functions

The sensitivity function has a more formal counterpart in the influence function, which is defined as a derivative of a statistical functional. In many cases it is simply the limit as the sample size n tends to infinity of the sensitivity function computed for a sample generated from a fixed model.

Examples

Let $y_1, \ldots, y_n$ be a sample from some cumulative distribution F with expectation μ_F. As n increases, the sensitivity function of the arithmetic mean converges to the influence function, which is $\mathrm{IF}_F(u) = u - \mu_F$. The influence function of the trimmed mean obtained by trimming a proportion α of the largest and the smallest observations is

$$\begin{aligned}\mathrm{IF}_F(u) &= u - qF\left(\frac{1}{2}\right)/(1-2\alpha), \quad \text{for } qF(\alpha) \le u \le qF(1-\alpha)\\ &= \mathrm{sign}\left(u - qF\left(\frac{1}{2}\right)\right)\left(qF(1-\alpha) - qF\left(\frac{1}{2}\right)\right)/(1-2\alpha),\\ &\quad \text{otherwise}\end{aligned}$$

This formula is correct for symmetric densities f. The symbol $qF(\alpha) = F^{-1}(\alpha)$ denotes the α-quantile of the distribution function.

The influence function is very similar to the sensitivity function and can thus be interpreted similarly. In particular, the gross error sensitivity is

$$\gamma_F^* = \sup_y |\mathrm{IF}_F(y)|$$

It has other uses that can be extremely helpful. It turns out that the squared influence function of an estimator is directly linked to its asymptotic variance. If our stochastic model stipulates that the observations $Y_1, \ldots, Y_n$ are independent and identically distributed with distribution F_θ for some real parameter θ, one can show that most estimators T of θ satisfy the following approximate relationship:

$$T(Y_1, \ldots, Y_n) \approx \theta + \mathrm{ave}(\mathrm{IF}_{F_\theta}(Y_i))$$

If this approximation is sufficiently precise, it implies that the asymptotic variance of the estimate T is

$$\mathrm{Var}_{\mathrm{asy}}(T) = \int (\mathrm{IF}_{F_\theta}(r))^2 f_\theta(r)\,\mathrm{d}r$$

which is, the expected value of the squared influence function. In this case, one can also apply the central limit theorem to conclude that

$$P(T \le t) \approx \Phi\left(\frac{\sqrt{n}(t-\theta)}{\sqrt{\mathrm{Var}_{\mathrm{asy}}(T)}}\right)$$

where Φ denotes the normal distribution function with density $\varphi(t) = \exp(-t^2/2)/\sqrt{2\pi}$. This in turn shows that

$$\left[T \pm 1.96\sqrt{\mathrm{Var}_{\mathrm{asy}}(T)}/\sqrt{n}\right]$$

is an approximated 95% confidence interval for θ. And finally, the arithmetic average of the squared influence evaluated at the observations is an estimate of the asymptotic variance. Equation [5] gives an example.

Breakdown and High Resistance

A limitation of the influence function is its local nature. It is based on the change of the value of the estimator from one sample to another one that differs by adding a single 'contamination.' The breakdown point is the simplest global measure of robustness. It is the largest percentage of wild values in a data set that an estimator can tolerate without giving wild estimates. This notion is inspired by the trimmed means, computed as the mean of a sample after deleting $100\alpha\%$ of the largest and of the smallest data points. This estimator has a breakdown point of $100\alpha\%$, since any contamination by wild data below this fraction is being trimmed. A special case of the trimmed means is the median, which for an odd-sized sample $(n = 2k+1)$ has a breakdown point of $k/n \approx 50\%$. This is so, because the median is computed as the $k+1$st value in the sample and anything less than k wild values will not lead to a wild estimate. More generally, global indicators describe the properties of an estimator under contamination of a sizable portion of the data.

A simple stochastic models that embraces outlying values among random errors are the so-called contaminated distributions of the form $(1-\varepsilon)F + \varepsilon H$. This is a mixture of a 'good' part F and a 'bad' part H. The contaminated normal distribution $(1-\varepsilon)$ Normal $(0, 1) + \varepsilon$ Normal $(0, \sigma^2)$, for example, describes random errors that can either result from a standard normal distribution, or from a normal distribution having a larger variance $\sigma > 1$. As ε grows from 0 to 50%, a larger and larger fraction of the data is expected to exhibit a distinct behavior. A global robustness indicator for estimators is based on behavior under positive fractions ε, whereas local properties, such as the influence function, merely consider limits as ε tends to zero.

An estimator with a breakdown point of 50% is called highly resistant. Such estimators can be very revealing when applied to data containing a large proportion of outliers, because they lead to a clear separation of the 'good' and the 'bad' data. The median is an example of a highly resistant location estimator. In a previous example, we computed the arithmetic mean of the three observations (14.0%, 13.7%, 26.3%) as being 18%. The corresponding residuals are equal to (14.0% − 18.0% = −4.0%, −4.3%, 8.3%). The median of the three observations is equal to 14%, with residuals (14.0% − 14.0% = 0.0%, −0.3%, 12.3%). The highly resistant median produces residuals that make it immediately evident that the third observation is a wild value. The ability of estimators to reveal hidden outliers is explained by the fact that they have bounded sensitivity with regard to single observations, but also, and more importantly, that even a largish fraction of outliers does not exert an undue influence on the estimate.

Another example of a highly resistant estimators is the median absolute deviation (MAD), defined as.

$$\mathrm{MAD}(y_1, \ldots, y_n) = \mathrm{median}(|y_1 - m|, \ldots, |y_n - m|)$$

where m denotes the median of the observations, $m = \mathrm{median}(y_1, \ldots, y_n)$. The MAD can be used instead of the standard deviation as an estimate of σ. (If we want consistency at the normal model, it has to be multiplied by 1.48.) In the example above of the three percentages, the MAD is equal to the median of the absolute values of the residuals, that is, MAD = 0.3%.

Robust Estimators

Least-Squares, Maximum Likelihood, and M-estimators

Least-squares estimators minimize the sum of squared residuals

$$T(y_1, \ldots, y_n) = \arg\min_{\boldsymbol{\theta}} \sum_{i=1}^{n} (y_i - \mu_i(\boldsymbol{\theta}))^2$$

that is, the estimated value is equal to the value of the parameter that minimizes the sum of squares. The parameters may form a vector, which is the reason for setting it boldface. As a general rule, least-squares estimators should be avoided because they have unbounded influence and a breakdown point of 0%. Maximum likelihood estimators (m.l.e.) for independent data are based on a stochastic model with density $f_i(x, \boldsymbol{\theta})$ for the ith observation and with $\boldsymbol{\theta}$ as the unknown vector of parameters. The m.l.e. is defined as

$$T(y_1, \ldots, y_n) = \arg\max_{\boldsymbol{\theta}} \sum_{i=1}^{n} \log\left(f_i(y_i, \boldsymbol{\theta})\right)$$
$$= \text{solution of} \left(\sum_{i=1}^{n} \frac{\partial}{\partial \boldsymbol{\theta}} \log\left(f_i(y_i, \boldsymbol{\theta})\right) = 0 \right)$$

that is, the estimator maximizes the logarithm of the likelihood. These estimators can be sensitivity robust, depending on the properties of the densities f_i. But if we use normal, poisson, or binomial models, as is mostly the case, they do not improve on the least-squares estimates.

Generalizing either of these two concepts is the M-estimator, defined by

$$T(y_1, \ldots, y_n) = \arg\min_{\boldsymbol{\theta}} \sum_{i=1}^{n} \rho_i(y_i, \boldsymbol{\theta})$$

that is, the estimator minimizes an arbitrary sum of functions. Usually, and for computability, the function $\rho_i(y_i, \boldsymbol{\theta})$ is convex in the parameter vector, but otherwise quite free. The corresponding estimating equation for computing the estimator $\boldsymbol{T}$ is

$$\sum_{i=1}^{n} \psi_i(y_i, \boldsymbol{T}(y_1, \ldots, y_n)) = 0$$

where $\psi_i(y, \boldsymbol{\theta}) = \frac{\partial}{\partial \boldsymbol{\theta}} \rho_i(y_i, \boldsymbol{\theta})$.

Example

Consider the linear regression case in which $\mu_i(\boldsymbol{\theta}) = \boldsymbol{x}_i^T \boldsymbol{\theta}$ is a linear combination of the covariates (which must include a constant value 1, if a constant is part of the regression equation). The superscript T will be used from now on to indicate the scalar product between two vectors. The model-based m.l.e. then has densities $f_i(y_i, \boldsymbol{\theta}) = f(y_i - \boldsymbol{x}_i^T \boldsymbol{\theta})$, where $f(r)$ is the density of the random errors and the function $\rho(r, \boldsymbol{\theta})$ finally is of the form $\rho_i(y_i, \boldsymbol{\theta}) = \rho(y_i - \boldsymbol{x}_i^T \boldsymbol{\theta})$. It follows that the derivative with regard to the parameters is $\psi_i(y_i, \boldsymbol{\theta}) = \psi(y_i - \boldsymbol{x}_i^T \boldsymbol{\theta}) \boldsymbol{x}_i$ with $\psi(r) = \rho'(r)$. An M-estimator $\boldsymbol{T}$ of a vector of regression coefficients $\boldsymbol{\theta}$ thus satisfies the system of equations (one for each regression coefficient)

$$\sum_{i=1}^{n} \psi(y_i - \boldsymbol{x}_i^T \boldsymbol{\theta}) \boldsymbol{x}_i = 0 \qquad [1]$$

The M-estimator with $\rho(r) = r^2/2$ (rho-function) and $\psi(r) = r$ (psi-function) is equal to the least-squares estimator, which is also equal to the m.l.e. for random errors with a normal distribution. Any m.l.e. can be thought of as an M-estimator with $\rho(t) = -\log(f(t))$, but thinking in terms of M-estimators is an advantage and an important conceptual step since it frees us from any artificial constraints. Recall that the variance of the least-squares estimator with random errors with constant variance σ^2 is equal to

$$\sigma^2 \left(\mathrm{X}^T \mathrm{X}\right)^{-1}$$

where X denotes the matrix of the values of the covariates. For general M-estimators, the same type of expression holds for the asymptotic variance, except that σ^2 is replaced by

$$\frac{\int_{-\infty}^{\infty} \psi^2(r) f(r) \mathrm{d}r}{\left(\int_{-\infty}^{\infty} \psi'(r) f(r) \mathrm{d}r\right)^2} \qquad [2]$$

where $f(r)$ is the density of the random errors. The fact that the covariate part of the asymptotic variance remains unchanged shows that M-estimators of this type do nothing to control the leverage exerted by outlying values of the covariates. For this reason, these estimators have bounded influence and good breakdown behavior only if such outlying values are excluded. If arbitrary fictitious covariate values are considered, then the influence is also unbounded and the breakdown point is 0.

The M-estimators are defined by a rho-function and an associated psi-function. Boundedness of the psi-function is necessary for robustness. Careful tuning of the shape of the psi-function permits both robustness and efficiency. It is well-known that the least-squares estimator, which has psi-function $\psi(r) = r$, is optimally efficient when the error distribution is exactly Gaussian (i.e., normal). To preserve a high Gaussian efficiency, the psi-function should remain unaltered near zero, that is, $\psi(r) \approx r$ for small r. Three standard choices are given in Table 1. The M-equation [1] must be adapted to the scale of the random errors. This requires an estimate S of the residual scale, such as the MAD of the residuals and the M-equation becomes

$$\sum_{i=1}^{n} \psi\left(\frac{y_i - \boldsymbol{x}_i^T \boldsymbol{T}}{k \times S}\right) \boldsymbol{x}_i = 0 \qquad [3]$$

The multiplier k of the scale S can be any positive number and determines the loss of Gaussian efficiency, which is biggest for small k. The Huber and Tukey estimators give values very close to the least-squares estimator when k is large. This is not true for the least absolute deviations estimator which is unaffected by S and k. A reasonable compromise choice for the denominator $k \times S$ is $1.3 \times$ MAD (residuals) for the Huber estimator and $7 \times$ MAD (residuals) for the Tukey estimator. Some statistical packages offer the choice of robust regression estimators instead of the least-squares solution. An example is the reg function in the R package (reference).

Theoretical Justification of Huber's Estimator

A concise discussion of many of the topics discussed in this article can be found in the two books by Huber (1981,

Table 1 The Huber function satisfies $\psi_H(r) = r$ for r between -1 and 1 and outside of this interval, the function is constant equal to the sign of r. This gives an S-shape to this function. The Tukey function also satisfies $\psi_T(r) \approx r$ for small r and it also satisfies $\psi_T(-r) = \psi_T(r)$ as does the Huber function. However, the Tukey function is equal to zero for r bigger than 1 or smaller than -1 and thus decreases for some intermediate values of r. The Huber function is nondecreasing. Minimizing the absolute deviation leads to a ψ-function with a jump at the origin where the values go abruptly from -1 to 1. It does not satisfy $\psi_A(r) \approx r$ from small r and it does indeed suffer from fairly poor efficiency when the random errors follow a normal distribution

Name	*Psi-function*
Huber-estimator	$\psi_H(r) = \min(1, \max(r, -1))$
Tukey-estimator	$\psi_T(r) = r(1 - \min(r^2, 1))^2$
Least absolute deviations	$\psi_A(r) = \mathrm{sign}(r)$

1996). Huber's location estimators T_k in the case of known scale ($S = 1$) are solutions of

$$\sum_{i=1}^{n} \psi_H\left(\frac{y_i - T_k(y_1, \ldots, y_n)}{k}\right) = \sum_{i=1}^{n} \psi_k(y_i - T_k(y_1, \ldots, y_n))/k = 0 \quad [4]$$

where

$$\psi_k(r) = \min(k, \max(-k, r)) = \begin{cases} -k, & \text{if } t \le -k \\ t, & \text{if } -k < t \le k \\ k, & \text{if } t > k \end{cases}$$

This is an m.l.e. for random errors with density $f_{k(t)}$ which is normal-like in the center and has tails that decrease exponentially. These models for random errors were discovered by Huber and have been discussed in his seminal paper (Huber, 1964). Huber showed that f_k is in some mathematical sense the worst among all contaminated densities with a contaminating fraction of ε_k. As a consequence, the corresponding Huber estimator T_k is the estimator that best protects against a contamination of $100\varepsilon_k\%$ of the data. The Huber estimator is therefore the best one in a global sense. Even if a sizable portion of the data contains no useable information, this estimator will perform as well as be possible under these circumstances.

Indicators of robustness such as the breakdown point and the gross error sensitivity generate similar optimality questions as the one solved by Huber (1964). One is interested, for example, in finding an estimator that satisfies the two conditions of consistency and bounded gross error sensitivity and, given these conditions, is most precise. This problem is of a local nature, because we do not consider sizable fractions of outliers, but rather limits for very small fractions. The problem is again solved by the Huber estimators, which shows – not very surprisingly – that a globally best estimator is also locally best. The estimators T_k form a family of least variable estimators with gross error sensitivities that increase as k increases. In other words, they provide a bridge between the median ($k = 0$) and the arithmetic mean ($k = \infty$) and between a minimal value of the gross error sensitivity and an infinite gross error sensitivity. Considering only local properties defined by the influence function has the advantage of being more easily generalized. Thus, it is possible to solve a variety of problems of this type. The book by Hampel et al. (1986) provides a detailed discussion of related results.

Redescending M-Estimators and Highly Resistant Regression Estimators

The form of the Huber estimator comes as a surprise because it never entirely rejects gross errors among the observations. In order to completely reject such outliers, the psi-function $\psi(r)$ would have to be equal to zero for sufficiently large $|r|$. Such an estimator is called redescending, because the psi-function remains roughly linear near the origin, reaches a bound, and subsequently redescends toward zero. Clearly, the Tukey estimator is inspired by this insight. Because ψ_T is not an increasing function, the estimating eqn [1] of the biweight estimator may have multiple solutions. The estimate is thus not well defined. However, among all the solutions of the estimating equations, an appropriate one can usually be picked out by looking at the resulting residuals. Also, when multiple solutions do exist, several of them may be of interest.

Redescending M-estimators are also of interest in the search for highly resistant regression estimators, because they have the potential to identify and eliminate outliers with high leverage. The so-called S-estimators are an implementation of this idea (reference).

Rousseeuw's least-median-of-squares (LMS) estimator is another highly resistant regression estimator. It is defined by the criterion.

$$\text{criterion}(\boldsymbol{T}) = \text{median}\left\{\left(y_1 - \boldsymbol{x}_1^T\boldsymbol{T}\right)^2, \ldots, \left(y_n - \boldsymbol{x}_n^T\boldsymbol{T}\right)^2\right\}$$

which can be seen as a modification of the least-squares criterion, since it replaces the sum by the median. The LMS estimator minimizes this criterion function. The LMS is a useful, often revealing, estimate. It is, however, quite unstable, not with regard to outliers, but with regard to other features of the data.

Finite Samples

A robust data analysis must be valid and efficient beyond a narrow set of circumstances. The classical regression estimator, for example, is chosen to be the best possible for normally distributed observations.

$$y_i = \boldsymbol{x}_i^T\boldsymbol{\theta} + \varepsilon_i, \quad \varepsilon_i \sim \text{Normal}\left(0, \sigma^2\right)$$

Robustness demands joint optimality for a broader set of error distributions. One way in which this can be achieved, is by choosing a finite number of challenges, in the simplest case a couple such as {Normal, Student's t with 2 degrees of freedom}, the idea being that the estimator would have to perform well, whether the errors were generated by one or the other of the distributions. For such a set of challenges, the performance of an estimator is determined by a set of efficiencies, one for each challenge. Typically, an estimator that is highly efficient for one of the challenges will have a low efficiency for all the others. Robust estimators on the other hand must have as high an efficiency as possible for all challenges. How to compute estimators that maximize jointly the whole set of efficiencies is discussed in Morgenthaler and Tukey (1991).

Iteratively Reweighted Least-Squares

The computation of the least-squares estimator is straightforward, because the estimating equation is linear. A program for computing the weighted least-squares solution is all that is needed to find the values of M-estimators. To illustrate the idea, we consider the solution of [2]. Rewriting the estimating equation as,

$$\sum_{i=1}^{n}\left[\frac{\psi_k(y_i - T_k(y_1, \ldots, y_n))}{y_i - T_k(y_1, \ldots, y_n)}(y_i - T_k \le (y_1, \ldots, y_n))\right] = 0$$

an algorithm immediately suggests itself. We could start with a reasonable guess T_k^0 for the value of T_k, such as the median of the observations. Next, we compute weights

$$w_i^0 = \frac{\psi_k(y_i - T_k^0)}{y_i - T_k^0}$$

and then solve the estimating equation, $\sum_{i=1}^n w_i^0(y_i - T_k(y_1, \ldots, y_n)) = 0$. From this, we obtain the next guess for T_k, viz.

$$T_k^1 = \sum_{i=1}^n w_i^0 y_i / \sum_{i=1}^n w_i^0$$

With this new value for T_k we are back at the start of the loop, ready to recompute the weights, and then the next value for T_k. Repeating the loop a fixed number of times or until convergence leads to practical values for M-estimates. This idea of iteratively reweighting reveals robust estimators as being weighted least-squares estimators with weights that are not predetermined by the user (as is the case in the weighted least-squares setting), but are automatically picked out by the algorithm. Inspecting the final weights reveals the observations that have been downweighted and allows the user to inspect them and investigate further the potential reasons for the low weight.

Other Estimation Problems

In order to explain the fundamental principles of robust statistics, I have focused mainly on the linear regression model. It is clear, however, that many other procedures much used in the social sciences are in need of robust alternatives.

Robust Inference

The sampling distributions of robust estimators can often be approximated sufficiently well by their asymptotic normal distributions. For the regression M-estimator the following formula gives an estimated variance matrix of the estimated regression coefficients.

$$\frac{n\sum_{i=1}^n (\psi(r_i))^2}{\left(\sum_{i=1}^n \psi'(r_i)\right)^2}\left(\sum_{i=1}^n \boldsymbol{x}_i \boldsymbol{x}_i^T\right)^{-1} \qquad [5]$$

where $r_1, \ldots, r_n$ are the residuals and $\boldsymbol{x}_i$ is the vector of covariate values for the ith observation. Using the approximate normality of the estimate, this equation allows one to compute robust confidence intervals for individual parameters. The robustness in the context of confidence intervals means that the coverage of the parameter is equal to the nominal coverage rate even under deviations from the model. Furthermore, the interval should not achieve this feat by being overly long.

Distribution-free tests are very resistant in one respect. Their size, that is the probability of falsely rejecting the null hypothesis, is stable. The power, however, depends of course on the distribution of the observations and need not be stable under changes to this distribution. Robust tests must have both, stable sizes and good power under a variety of circumstances. This point illustrates once more the fact that robustness and distribution-freeness are in general two distinct aspects of statistical inference.

Abstract

Carl R. Rogers (1902–87) was America's most influential psychotherapist and one of its most prominent psychologists. He developed an approach to psychotherapy, known successively as the 'nondirective,' 'client-centered,' and 'person-centered' approach. He pioneered in the recording and publishing of psychotherapy sessions and cases. He sponsored more scientific research on counseling and psychotherapy than had ever been undertaken. He was largely responsible for extending professional counseling and psychotherapy beyond psychiatry and psychoanalysis to many helping professions – psychology, social work, education, pastoral counseling, and others. Rogers was a leader in the humanistic psychology movement, encounter groups, and using effective interpersonal communication to resolve intergroup conflict.

Carl R. Rogers was America's most influential psychotherapist and one of its most prominent psychologists. His therapeutic approach, known most often as 'client-centered therapy' or 'person-centered therapy,' was validated through voluminous scientific research and taught widely, profoundly affecting the fields of counseling and psychotherapy throughout the world and permeating many other helping professions. A leader in the humanistic psychology movement of the later twentieth century, Rogers also extended his theory and practice to include person-centered approaches to education, group leadership, intergroup conflict, cross-cultural communication, and peace-keeping. His writings and personal example stimulated professional, social, and political change in many countries.

Client-Centered Therapy

Rogers' approach to counseling and psychotherapy was based on a core hypothesis about human growth and personality change, which he summarized in 1950:

> Client-centered therapy operates primarily upon one central and basic hypothesis which has undergone relatively little change with the years. This hypothesis is that the client has within himself the capacity, latent if not evident, to understand those aspects of his life and of himself which are causing him pain, and the capacity and the tendency to reorganize himself and his relationship to life in the direction of self-actualization and maturity in such a way as to bring a greater degree of internal comfort. The function of the therapist is to create such a psychological atmosphere as will permit this capacity and this strength to become effective rather than latent or potential (p. 443).

While other therapies might profess similar beliefs, Rogers' method of creating the therapeutic psychological atmosphere was radically different from other approaches commonly employed. Avoiding questions, interpretation, or other directive techniques, Rogers' initial 'nondirective' method relied exclusively on careful listening and skillful 'reflection of feelings,' leading to client insight and positive action. Although he always remained primarily nondirective in his practice, Rogers soon recognized that the counselor's attitudes of acceptance and understanding were more important than his particular techniques. Still later he clarified that it was the relationship in therapy, which the attitudes helped create, that was growth-producing. Rogers called this therapeutic relationship 'client-centered' and described three 'core conditions' in the relationship which bring about positive change in clients.

The first is to accept the client as he is, as a person of inherent worth possessing both positive and negative feeling and impulses. Adopting a term coined by his student Stanley Standal, Rogers called this acceptance and prizing of the person 'unconditional positive regard.' The second is "the therapist's willingness and sensitive ability to understand the client's thoughts, feelings and struggles form the client's point of view…to adopt his frame of reference" (1949: 84). Rogers used the term 'empathy' to describe this condition, popularizing a concept already in use in the field. The third is, be "genuine, or whole, or congruent in the relationship…It is only as [the therapist] is, in that relationship, a unified person, with his experienced feeling, his awareness of his feelings, and his expression of those feelings all congruent or similar, that he is most able to facilitate therapy" (pp. 199–200). He most often used 'congruence' to describe this third ingredient of the therapeutic relationship.

When a counselor is in psychological contact with a client and is able to communicate these attitudes so that the client can perceive them, the 'necessary and sufficient conditions for therapeutic personality change' are present. Rogers argued and demonstrated that the client has within himself the ability and tendency to understand his needs and problems, to gain insight, to reorganize his personality, and to take constructive action. What clients need is not the judgment, interpretation, advice, or direction of experts, but supportive counselors and therapists to help them rediscover and trust their 'inner experiencing' (a concept borrowed from Gendlin), achieve their own insights, and set their own direction.

Until Rogers, the fields of counseling and psychotherapy had been dominated by the guidance movement and psychoanalysis, respectively. While Rogers was not the first to argue for a 'newer approach' to counseling and psychotherapy – an approach that relied less on the professional's expertise and direction and more on the client's direction and resources – Rogers' system was arguably the most clearly described,

comprehensive, and extreme, and the newer direction in mental health work became associated with him.

Recording Therapy

One reason Rogers was able to demonstrate his propositions in a cogent and convincing manner was that he was the first person in history to record and publish complete cases of psychotherapy. Before the invention of tape recorders this was a remarkable achievement, requiring a microphone in the counseling room connected to alternating phonograph machines in an adjoining room, which cut grooves in blank record disks that had to be changed every 3 minutes. With his student Bernard Covner, Rogers and his team recorded thousands of disks, involving scores of clients. These recordings were pivotal in the clinical training of psychotherapists which, in the 1940s, Rogers may have been the first to offer in an American university setting.

In addition to the audio recording of therapy sessions, Rogers was among the first to make cinematic recordings of counseling and psychotherapy. The American Academy of Psychotherapists became a leading distributor of training tapes and movies, with Rogers the most frequent therapist portrayed. A still widely distributed set of training films showed Rogers, Gestalt therapist Frederick (Fritz) Perls, and rationale-emotive therapist Albert Ellis each demonstrating his method with the same client, 'Gloria.'

Scientific Research and Theory

The recording of actual therapy sessions also provided the data on which Rogers and his colleagues carried out more scientific research on one therapeutic approach than had ever been undertaken before. Rogers and his students and colleagues devised and used numerous instruments for measuring the variables of client-centered therapy and its outcomes: therapist acceptance, empathic understanding, and congruence; client expression of feelings, insight, self-concept, self-acceptance, self-ideal, and level of experiencing; and clients' positive actions, social adjustment, and numerous other variables. In 1959 the American Psychological Association awarded Rogers its first Distinguished Scientific Contribution Award for "developing an original method to objectify the description and analysis of the psychotherapeutic process, for formulating a testable theory of psychotherapy and its effects on personality and behavior, and for extensive systematic research to exhibit the value of the method and explore and test the implications of the theory" (p. 128).

As the scientific award citation suggests, Rogers was interested in psychological theory and in the effects of therapy on personality as well as behavior. Building upon the Gestalt and phenomenological movements in psychology, and the work of his students Victor Raimy and Arthur Combs, he developed a 'self-theory' of personality which is still included in many textbooks (Rogers, 1959). The theory describes how an individual's concept of self emerges, how the process of socialization causes individuals to distrust their feelings and sense of self, how experiences that are inconsistent with the concept of self become denied and distorted, causing personal distress and psychological problems, and how the therapeutic relationship can help the individual restructure the sense of self, allowing previously denied and distorted experience into awareness, leading to reduction in stress and openness to new experiencing.

Initial Impact on the Professions

More than any individual Rogers was responsible for the spread of professional counseling and psychotherapy beyond psychiatry and psychoanalysis to other helping professions. While he was not the first to use the term 'client' for the recipient of therapy, he popularized it, emphasizing that a person seeking help should not be treated as a dependent patient but as a responsible client, and that those in psychological distress were not necessarily sick requiring treatment by medical specialists. Rather all people could be helped by the growth-producing conditions of empathic understanding, unconditional positive regard, and congruence, and professionals from many walks of life could be trained to provide these conditions. Thus counselors, psychologists, social workers, clergy, medical workers, youth and family workers, and other helping professionals could employ counseling methods and client-centered attitudes in their work. Rogers' books *Counseling and Psychotherapy* (1942) and *Client-Centered Therapy* (1951) described the principles of effective therapy and presented ample case studies from recorded sessions to illustrate his points.

Rogers also impacted the helping professions through leadership in many professional associations. Earlier in his career he served on the executive committee of American Association of Social Workers and was vice-president of American Association of Orthopsychiatry (social workers). As he became more prominent in the psychology profession, he served as president of American Association of Applied Psychology, American Psychological Association, and American Academy of Psychotherapists, among other distinguished positions.

Applications to Other Fields

In his own counseling practice, teaching, administration, and writing, Rogers continued to apply his theory and method to other fields – education, parenting, group leadership, and the health professions, to name a few. In each instance he demonstrated how the facilitative conditions of empathy, positive regard, and congruence could unleash growth, creativity, learning, and healing in children, students, group members, patients, and others. Applied to education, his views on 'student-centered learning' coincided with and contributed to the 'open education' movement in the United States, Great Britain, and elsewhere. His book *Freedom to Learn* (1969) went through two new editions over the next 25 years.

He expanded his theory and practice into the areas of group leadership and group facilitation over several decades. In the 1940s he, Thomas Gordon, and colleagues at the University of Chicago had experimented with 'group-centered leadership,' whereby the leader's acceptance, understanding, genuineness,

and willingness to let the group set its own directions stimulated great energy, creativity, and productivity among group members. In the late 1950s and 1960s, Gordon, Richard Farson, Rogers, and associates extended this approach to what Rogers called the 'basic encounter group' – an unstructured group experience in which 'normal' group members came to greater self-understanding, spontaneity, improved communication, and genuineness in relationships. Rogers led scores of encounter groups in professional, business, religious, medical, academic, personal growth, and other settings. *Look* magazine called Rogers an 'elder statesmen of encounter groups.' *Carl Rogers on Encounter Groups* (1970) was a major seller, and his and Farson's film of an encounter group they facilitated, 'Journey Into Self,' won an Academy Award (an 'Oscar') for the best feature-length documentary in 1968.

He applied his approach to couples' relationships in *Becoming Partners: Marriage and Its Alternatives* (1972). Through case studies of couples in varying types of relationships – from traditional to openly experimental – he demonstrated how open communication, genuineness, mutual support for the partner's growth, and acceptance of change were ingredients for healthy relationships. Similarly, in earlier articles on 'The Nature of Man' and 'A Therapist's View of the Good Life: The Fully Functioning Person,' and later essays like those collected in *A Way of Being* (1980), he posited a philosophical–psychological model of the 'person of tomorrow' or 'the emerging person' – an individual who is open to the outer world but also deeply connected to one's own inner experience, who trusts one's own organismic valuing process, who is authentic, who is skeptical of authority, science, and technology, who values wholeness, and who understands that life is an ongoing process of change, among other qualities.

Political Implications

Beyond the psychological and philosophical realms, Rogers eventually recognized the political implications of his theories and methods – not in the sense of partisan politics, but in how power and influence are distributed in all human relationships. He explored these in *Carl Rogers on Personal Power* (1977). He and others had always recognized that, in the counseling or therapy relationships, the client-centered approach reversed the power relationship implicit in the traditional medical model. The expert who prescribed treatment was now the facilitator of growth who followed the client's lead. Gradually it became apparent that Rogers was arguing for a similar shift in power relations in other professional and human relationships. Recognizing the ever-widening applicability of the client-centered, student-centered, and group-centered approach, Rogers increasingly used a broader term, 'person-centered,' to describe his work.

The shift was not just semantic; it took the work in new directions. In the 1970s and 1980s he experimented with applications of the person-centered approach to enhancing cross-cultural communication and resolving intergroup and international conflict. Through workshops and filmed encounter groups involving different races, generations, and political persuasions – including Catholic and Irish protagonists from Northern Ireland – Rogers demonstrated how the same growth-promoting conditions useful in all helping relationships can lead to improved communication and greater understanding among previously antagonistic parties. He and his colleagues led person-centered workshops for groups from 100 to 800 participants in Brazil, Mexico, Spain, Hungary, Soviet Union, and many other countries. In South Africa, for example, Rogers facilitated demonstration encounter groups before large audiences in which, for the first time in their lives, white and black South Africans could actually communicate with one another in an atmosphere of equality and respect.

A 4-day gathering of international leaders in Austria on resolving tensions in Central America was a laboratory demonstration of the potential of the person-centered approach for resolving real international conflict. At the invitation of the Carl Rogers Peace Project, over 40 participants – including three former presidents of Central American countries, a current vice-president, seven ambassadors, current and former US senators and representatives, representatives of the Contra and Sandanista warring factions, and others – sat together as 83-year-old Rogers and his colleagues facilitated an unprecedented level of open communication among the participants. Former Costa Rican President Rodrigo Carazo later credited Rogers and his group for breaking the stalemate and allowing the peace process in Central America to move forward and eventually succeed. Other testimonials suggested that Rogers' efforts in professional development and citizen diplomacy helped influence future developments in several countries. In acknowledgment of his work, Rogers was nominated posthumously for the Nobel Prize for Peace. At Rogers' memorial service, Richard Farson eulogized him as 'a quiet revolutionary.'

Humanistic Psychology

Rogers was a leader in what Abraham Maslow described as a 'third force' in psychology, which emerged as a visible and influential movement in the latter half of the twentieth century. 'Humanistic psychology,' as it came to be known, differed from psychoanalysis and behaviorism in at least three ways. First, this psychology gave much more emphasis and credence to the individual's 'phenomenal field' – e.g., the client-centered therapists trying to understand the client's frame of reference rather than evaluating or diagnosing from the outside, or the existential psychotherapists helping the patient find meaning in his life. Second, this psychology focused not just on the remediation of psychological problems, but on psychological health, creativity, self-actualization, or what Rogers described as 'the fully functioning person.' It was concerned not only with helping people adjust, but helping them experience their positive human potential to the fullest. Third, it was a psychology interested in those factors that distinguish human beings from other species. Choice, will, freedom, values, feelings, goals, and other humanistic concerns were all central subjects of study.

As Rogers' career and that of leading behavioral psychologist B.F. Skinner paralleled one another in their timing, productivity, and influence, their views inevitably were contrasted. Meeting on several occasions, including a 6-hour debate-dialogue in 1962, one of their exchanges on 'Some

Issues Concerning the Control of Human Behavior' (1956) became one of the most frequently reprinted articles in the behavioral sciences. Rogers became a leading spokesperson for the humanistic psychology movement. In that unofficial capacity, he was often asked to engage in dialogues with some of the leading theologians, philosophers, and intellectuals of the later twentieth century, including Martin Buber, Paul Tillich, Reinhold Niebuhr, Michael Polanyi, Gregory Bateson, Rollo May, Skinner, R.D. Laing, and others (Kirschenbaum and Henderson, 1989a). Humanistic psychology continues to exert a significant influence on society and the helping professions, including serving as precursor and foundation of the contemporary positive psychology movement.

Enduring Influence

While Rogers was still alive, he presented a vivid role model of the person-centered approach for almost six decades, demonstrating his theories through teaching, lecturing, live demonstrations and workshops, and audio–visual recordings. By virtually all accounts, he embodied his theories by being an exceptional listener and communicator and a decent, honorable person. Near the end of his career, 1982 surveys in the *Journal of Counseling Psychology* and *American Psychologist* still ranked Carl Rogers as the most influential author and counselor/psychotherapist.

Since his death in 1987, Rogers' influence has remained strong. In the United States, although cognitive–behavioral therapy has supplanted the person-centered approach as the leading therapeutic approach, Rogers still remains an influential figure. A survey of 2600 therapists in the *Psychotherapy Networker* in 2006 easily ranked Rogers as the respondents' most often cited influence.

Part of this is due to the continuing impact of his writings. Rogers was one of the helping professions' most prolific writers, authoring 17 books and more than 200 professional articles and research studies. Millions of copies of his books have been printed, including over 80 foreign language editions of his works. His most popular book *On Becoming a Person* (1961), written for both a professional and general audience, *The Carl Rogers Reader* (Kirschenbaum and Henderson, 1989b), and other works still in print continue to spread his ideas.

Around the world, person-centered psychotherapy continues to be a leading approach in many countries. One explanation may be that, of all the major counseling theories, the person-centered approach arguably is unique in having clear political implications – reversing traditional, hierarchal professional roles with more egalitarian relationships between helpers and clients, teachers and students, leaders and group members, and empowering counselors and therapists to work for conflict resolution and social change in their own communities and wider world. This has appealed to the segment of the helping professions, particularly in Europe, that is concerned about the wider social context in which counseling and therapy are practiced.

After Rogers' death some of the greatest new interest in his work has been in Eastern Europe, Russia, Latin America, and other emerging democracies. As a Japanese counselor explained in the 1960s, Rogers helped "teach me … to be democratic and not authoritative." The totality of his life's work was devoted to demonstrating how supportive, growth-producing conditions can unleash healing, responsible self-direction, and creativity in individuals and groups in all walks of life. As many countries strive to resolve old, intergroup tensions and put self-government and self-determination into practice, they have recognized in Rogers' work not only particular methods of use to counselors, teachers, helping professionals, and group leaders, but a positive, person-centered, democratic philosophy consistent with their national aspirations.

Meanwhile, in North America and elsewhere, Rogers' influence endures not only in the traditional client-centered approach to counseling and psychotherapy that Rogers promulgated and practiced, but in a number of new paradigms. For many practitioners and scholars around the world, the person-centered approach as described by Carl Rogers remains the only person-centered approach. In counseling and psychotherapy, this approach may be characterized by:

- A belief in the client's 'self-actualizing tendency'; that is, an innate motivation to grow and mature and realize his or her self-interest, especially when provided with a supportive environment.
- A reliance on the therapeutic relationship, characterized by the core conditions of congruence, empathy, and unconditional positive regard, for therapeutic progress.
- A continuing focus on the client's inner experience, hence ….
- An absence of directive techniques or perspectives introduced by the therapist, such as questions, interpretation, advice, coaching, and the like (except for relatively rare expressions of counselor congruence).
- An avoidance of diagnosis, treatment plans, and other therapist-centered methods that reflect the medical model of mental illness.
- A view of the client as a whole person in the process of 'becoming'; that is, becoming a more fully functioning person; therefore, counseling focuses not simply on a presenting problem but on more holistic change, so the client can continue to grow and exercise self-direction beyond the therapeutic relationship.

One might say these characteristics describe what has been called 'traditional,' 'classic,' or 'orthodox' client-centered/person-centered counseling and psychotherapy. Some simply prefer the term 'client-centered.' However, for many other practitioners and scholars, there is more than a single person-centered approach. They believe it is possible to introduce certain techniques to further a client's self-exploration while still remaining essentially person centered. Thus, Natalie Rogers, Carl Rogers' daughter, developed 'person-centered expressive therapy' which engages clients and group members in the creative arts and employs empathic listening to help them explore the meaning of their creative expression and its implication for their lives. Eugene Gendlin developed 'focusing' and 'focusing-oriented, experiential psychotherapy' as a method for helping clients tune into their 'inner experiencing' in greater depth, while continuing to use empathic listening as a primary method for furthering that exploration. Leslie Greenberg, Robert Elliott, and others developed 'process-experiential,' then 'emotion-focused therapy' which combined

Gestalt and other techniques to guide the therapeutic process. All three of these approaches – and others – have identified themselves as person centered and have significant followings around the world. Their proponents would argue that they remain essentially person centered, with a major emphasis on the core conditions, including a predominant use of empathic listening.

Thus, there is some controversy in the person-centered world today as to whether 'person centered' should be used exclusively to describe Rogers' traditional or classic approach to counseling and psychotherapy, or whether there is room for 'many tribes' in the person-centered nation. In some countries, such as the United Kingdom, classic client-centered counseling has been the predominant mode; in others, like Germany, other suborientations of the person-centered movement have commanded greater allegiance. Whatever the orientation, the person-centered approach is institutionalized in a number of European countries, with universities and training institutes turning out person-centered practitioners, robust research programs, government recognition for licensure, and reimbursement by insurance companies, although political turf battles around recognition and reimbursement are ongoing. There are scores of person-centered, professional organizations around the world, numbering in the hundreds to the thousands. One 2005 study showed that in the 15 years after Rogers' death, there were more publications on Rogers and the person-centered approach than in the 40 years before. This trend has continued.

Criticism

In 1972, Rogers was awarded the American Psychological Association's Distinguished Professional Contribution Award, becoming the first psychologist to receive both the organization's highest scientific and highest professional honor. He was recognized for "devising, practicing, evaluating and teaching a method of psychotherapy and counseling which reaches to the very roots of human potentiality and individuality … [H]e has caused all psychotherapists to reexamine their procedures in a new light." The committee also noted how Rogers' "commitment to the whole person has been an example which has guided the practice of psychology in schools, industry, and throughout the community. Innovator in personality research, pioneer in the encounter movement, and respected gadfly of organized psychology, he has made a lasting impression on the profession of psychology" (1973: 71).

Not everyone agrees that Rogers' lasting impression is a positive one. As critic Christopher Lasch once wrote, "As a founding father of humanistic psychology, the human potential movement and the encounter group, Carl Rogers has a lot to answer for." Critics of Rogers' work have argued that client-centered therapy is superficial, unworkable with some populations, and unmindful of multicultural and feminist issues, the social context, and recent advances in behavioral, drug, and alternative therapies; that Rogers' views on human nature are unrealistically optimistic and underestimate human evil; that encounter groups and humanistic psychology have fostered widespread selfishness, narcissism, and moral permissiveness; and that Rogers' experiments with organizational change were naive and counterproductive. Such criticisms have sometimes been fair; for Rogers, like any individual, was a product of his times, with personal and historical limitations. Just as often, criticisms of Rogers and his work have been wanting, because the critic was unfamiliar with the full scope of Rogers' theories, research, and ever-widening practice, or biased, because the critic's own politics were antagonistic to that of the explicitly egalitarian, progressive politics of the person-centered approach.

Critics notwithstanding, Rogers more than anyone helped spread professional counseling and psychotherapy beyond psychiatry and psychoanalysis to psychology and other helping professions. Interestingly, as meta-analyses of psychotherapy research continue to emerge, the data increasingly suggest that the success of counseling and therapy is not due to any particular method, whether cognitive behavioral, psychodynamic, client-centered, or other. Rather the research demonstrates that there are a number of 'common factors' in the context of the therapy relationship which account for successful outcomes. Many of these common factors point back to the therapist's support, empathic understanding, and ability to form a therapeutic alliance with the client. Ironically, Rogers' core conditions for therapeutic change, decades later, are being validated by the latest generation of scientific research. While this research suggests that positive regard, empathy, and congruence may not be absolutely necessary in every case nor sufficient for all counseling relationships, what the research does affirm are: first, Rogers' initial insights about the importance of the therapeutic relationship; second, the usefulness and practicality of the core conditions for forming the essential therapeutic alliance; and third, the efficacy of empathy and positive regard/acceptance, and, possibly, congruence for achieving positive counseling outcomes. Consequently, in recent years virtually all therapeutic approaches have come to acknowledge the importance of the therapeutic relationship and more intentionally incorporate it into their practice.

Education and Influences

Rogers attended the University of Wisconsin in Madison, first majoring in agriculture and then switching to history after experiencing the call to religious work. As one of 10 U.S. delegates to the 1922 World Student Christian Federation Conference in Peking (Beijing), he subsequently participated in a 3-month lecture tour to youth groups around China and Japan, all of which helped to liberalize his religious and social views. Back home, motivated by the 'social gospel' as much as religious conviction, he eschewed his parents' dogmatism and attended liberal Union Theological Seminary in New York City, which allowed him to take courses at adjoining Teachers College, Columbia University. There religious doubt combined with fascination with psychology. Influenced by instructors Leta Hollingworth, Goodwin Watson, William Heard Kilpatrick, the leading proponent of John Dewey's progressive education philosophy, and others, Rogers transferred to Teachers College to pursue a doctorate in clinical psychology. His exposure there to the testing and measurement movement of E.L. Thorndike was balanced by his experiences in clinical work and a fellowship at the Institute for

Child Guidance, where he encountered Freudian thought, a lecture by Alfred Adler, Rorschach testing, and other psychoanalytic and psychiatric approaches.

Seeking to integrate these influences, Rogers came to appreciate the importance of attending to and honoring clients' inner experience while also striving to objectively assess any changes that might result from treatment. His doctoral dissertation, *Measuring Personality Adjustment in Children Nine to Thirteen Years of Age* (1931), combined both subjective and objective measures. Rogers' 'Personality Adjustment Inventory' subsequently was published by YMCA Press and used for over 50 years. His next major learning experience was the 12 years of working with thousands of troubled children and adults in Rochester, New York, where he gradually developed his nondirective approach to counseling and psychotherapy. During this period, he was influenced by students of Otto Rank, especially Jessie Taft whose 'relationship therapy' shifted emphasis from past content to a focus on the patient's self-insight and self-acceptance within the therapeutic relationship. Throughout his life, Rogers frequently cited his students and younger colleagues as being significant influences on his work – challenging his assumptions, introducing him to new thinking and practice, and helping him remain on the cutting edge.

Positions Held

After leaving Columbia, Rogers' first position was at Rochester (NY) Society for the Prevention of Cruelty to Children (1928–38) where he was director of the Child Study Department, then director of the Rochester Guidance Center (1939–40). Based on his practical experience and first book, *Clinical Treatment of the Problem Child* (1939), he was offered a full-professorship at Ohio State University, where he taught from 1940 to 1944. After an interim year of training United Service Organization workers in counseling techniques with returned servicemen, he moved to University of Chicago, where he developed and ran the internationally renowned Counseling Center and taught in the Psychology Department from 1945 to 1957. He served a joint appointment in the Departments of Psychology and Psychiatry at the University of Wisconsin from 1957 to 1963. Somewhat burned out with academia and attracted by the warm weather and freedom of the 1960s human potential movement in California, he moved to the Western Behavioral Sciences Institute (WBSI) in La Jolla, California in 1963, where he was able to pursue his own interests and spend more time traveling for professional engagements around the world. In 1972, after a painful schism at WBSI he and other colleagues split off to form their own organization, Center for Studies of the Person, where Rogers remained until his death in 1987.

Personal Life

Rogers grew up in suburban Oak Park, then rural Glen Ellen, Illinois, with three brothers, a sister, and conservative, Protestant parents. Spending teenage years on the family farm, he developed a love of nature and serious working knowledge of scientific method, conducting agricultural experiments on a plot he and his brothers were responsible for. Upon college graduation he married childhood friend Helen Elliott (1901–79), an aspiring commercial artist, commencing a 55-year union. Their two children, David (1926–94) and Natalie (b. 1928) distinguished themselves professionally, David in medicine (e.g., Dean of Medicine at Johns Hopkins and president of the Robert Wood Johnson Foundation) and Natalie as an author and pioneer of 'client-centered expressive therapy' in the field of art therapy. For many years Rogers spent the academic winter quarter in the Caribbean and Mexico, where he read widely and developed a number of his theories, Helen painted, and both snorkeled. They regularly traveled to Rogers' professional engagements around the world and to be with their children and six grandchildren. Carl pursued lifelong hobbies of photography, making mobiles, and gardening. When Helen became ill in her seventies, Carl cared for her for several years until her death in 1979. Thereafter he remained involved in work, cultivated old and new friendships with both men and women, and traveled widely. He was active until his death at age 85 from a heart attack stemming from hip surgery following a fall.

While Rogers was by and large an excellent exemplar of his own theories about growth, change, and the fully functioning person, and while he led a rich and rewarding life in many respects, he was not without personal problems. He and Helen struggled with relationship issues in their later years, periodically causing unhappiness for both. Privately he suffered from alcohol dependency for several decades, although remarkably it appeared to have little or no effect on his work or relationships.

After Rogers left the church in his early twenties, he showed little or no interest in religion for most of his life. Yet in his seventies and eighties, surrounded by younger colleagues and family involved in various spiritual movements and practices in California, Rogers and Helen experimented with spiritualism and the paranormal, and he thought and wrote seriously on the nature of reality. Although he never had a significant religious or mystical experience himself in his later years, his spiritual journey did lead him to extend his concept of an actualizing tendency in individuals to a 'formative tendency in the universe,' his last theoretical formulation.

Abstract

Stein Rokkan (1921–79), Norwegian, was one of the world's leading social scientists after World War II. He played a unique role in organizing international social science cooperation in the 1960s and 1970s, and was the driving force in the development of infrastructure services for comparative research. But he was also a prolific writer, and it was the combination of all his contributions to comparative research, international cooperation, and infrastructure development that made him the comparativist of his time.

Stein Rokkan was one of the world's leading social scientists after World War II. He played a unique role in organizing international social science cooperation in the 1960s and 1970s, and was the driving force in the development of infrastructure services for comparative research. But he was also a prolific writer, and it was the combination of all his contributions to comparative research, international cooperation, and infrastructure development that made him the comparativist of his time.

Stein Rokkan, the Norwegian

Rokkan was born 4 July 1921 in Vågan on the Lofoten Islands, on the northern periphery of Norway, and grew up in Narvik. Between 1938 and 1948 he attended the University of Oslo, where he first studied philology and then political philosophy, in which he received his doctorate with a dissertation on David Hume. From 1948 to 1951 Rokkan continued his studies in the USA and England: at Columbia University, where his work with Paul Lazersfeld acquainted him with the methods of modern social research, and at the London School of Economics, where he met T. H. Marshall, whose historical-sociological research profoundly influenced his own.

Rokkan's educational career already contained the seeds of a rare combination of highly diverse talents: above all his great openness towards the 'new' social sciences while maintaining a firm grounding in the 'old' cultural sciences. His extensive linguistic, philosophical, and historical studies gave him a keen eye for the significance of cultural differences in international comparison, and thus for the often misleading simplicity of purely quantitative approaches. At the same time he recognized the potential of such approaches in comparative research and became one of their most important supporters. Rokkan's thought was interdisciplinary from early on. His scholarly interests included the entire spectrum of the social sciences, and this characterized his core scientific work: a political sociology in the tradition of classic macrosociology, the historical-comparative analysis of whole societies and polities.

From the very beginning, Rokkan combined a genuine international orientation with a deep devotion to his homeland that shaped his comparative approach. From his intimate knowledge of Norway he developed concepts (e.g., the center–periphery dichotomy) and questions (e.g., on the interaction of mass movements and institutional change) that he then applied to comparative research. This made him aware of the complexity of each single 'case' and led him to assess realistically the possibilities and limits of international comparisons.

Rokkan developed his system of thought, which was rooted in his origin and education, systematically throughout his entire scholarly career until his early death on 22 July 1979 in Bergen. From 1951 to 1958 he worked at the Institute of Social Research in Oslo, where he soon became engaged in various comparative research projects. In the same period he initiated, together with Henry Valen, the Norwegian Program of Electoral Research which was oriented on the work of the Survey Research Center in Ann Arbor, Michigan, but already showed Rokkan's signature in its emphasis on context variables.

In 1958 Rokkan became research professor at the Christian Michelsen Institute in Bergen, where in 1966 he was awarded a university chair and founded a new department of comparative politics. During this time he was also engaged in efforts to increase cooperation between the Scandinavian countries, which resulted in the publication of *Scandinavian Political Studies* since 1966, and in the founding of the Nordic Political Science Association in 1975.

Rokkan and the Internationalization of the Social Sciences

Rokkan was active at the international level from the very beginning of his professional career. Developing international research programs, organizing international projects and conferences, and building institutions and infrastructures for comparative research became the focus of his activities from the early 1960s. Three contexts of these activities can be distinguished: UNESCO and the International Social Science Council, the International Committee on Political Sociology, and the European Consortium for Political Research.

Rokkan, then Secretary-General of the International Sociological Association, participated in the founding of the International Social Science Council (ISSC) by UNESCO in 1952. In 1961, he proposed to the ISSC a broad program in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61114-5

cross-national and cross-cultural research which he then directed for over 15 years. He became a member of the Executive Committee of the ISSC in 1965 and served as president of the ISSC from 1973 to 1977.

The 1961 program led to a broad spectrum of activities to develop infrastructure services for comparative research and to promote concerted interdisciplinary research. Whole series of conferences were organized on comparative survey research and aggregate statistical comparisons of nations in the first half of the 1960s. Some of the further work was channeled into the European Coordination Centre for Research and Documentation in Social Sciences, set up in Vienna in 1963; other activities were headed up by two ISSC standing committees for data archives and comparative research established in 1966–67. Rokkan remained the driving force behind most of the subsequent activities, which in the 1970s also included summer schools and workbooks for training on comparative analysis and the promotion of an International Federation of Data Organization.

In the late 1960s, with the support of UNESCO Rokkan launched another series of conferences on national developments, asking what conclusions could be drawn from the early European experiences of state formation and nation-building for developmental processes outside Europe. Rokkan here developed his basic ideas about a macromodel of European political development. This work was also linked to the International Committee on Political Sociology that Rokkan, together with Shmuel Eisenstadt, Morris Janowitz, and Martin Lipset, had founded in 1960 and for which he served as Secretary from 1960 to 1970. Originally affiliated only with the International Sociological Association, in which Rokkan was vice-president from 1966 to 1970, it became a joint ISA/IPSA committee in 1970 when Rokkan was elected president of the International Political Science Association. During the 1960s the committee was an exclusive group of international scholars with a common interest in studying major historical changes. It was in this second context that Rokkan developed his ideas on democratization, cleavage structures, and party systems.

The third context was the European Consortium for Political Research. Rokkan was one of its founders and its first Chair from 1970 to 1976. Here too he pursued his central goals of developing joint research programs and improving infrastructure in the broadest sense: from bibliographic tools, research documentation, and data archives to computer applications (including cartography), and the training of the next generation of social scientists.

Rokkan's decisive role in the internationalization of the social sciences and the promotion of comparative research resulted from a congruence of personality and historical situation. In the 1960s the social sciences were expanding rapidly in Western Europe, but they suffered from national fragmentation. International cooperation was needed, and succeeded first via the USA. Only later did a genuine 'Europeanization' begin. Rokkan's broad education and international orientation proved invaluable in building bridges between the USA and Europe and reconciling different European traditions. His enormous talent for combining personal networking and institution-building was a crucial asset in this start-up phase and the close linkage he saw between programmatic conceptualization, cooperative organization, and infrastructure-building gave this endeavor a cohesiveness that seems to be lacking today.

Rokkan's historical role has somewhat overshadowed his scientific contributions, apart from a few famous single hypotheses and typologies. His lasting contribution will be his attempt to develop a macro-model of the political development of Europe. In particular, his comparative studies on the structuring of European mass democracies, and his analyses of the processes of state formation and nation-building in Europe, but also his general approach to comparative research.

The Structuring of Mass Politics in Western Europe

Rokkan's work on the democratization of the European nation-states concentrated on the institutional and organizational variations in the structuring of mass politics up to World War II. Here he developed his well-known ideas of four institutional thresholds of democratization and of historical cleavage structures which in the process of democratization are transformed into party systems via the formation of alliances and oppositions.

In institutional terms, democratization for Rokkan meant the successive lowering or removal of four thresholds: the threshold to political opposition (legitimation), to political participation (incorporation), to access to parliament (representation), and to participation in government (executive power).

The lowering of the first two thresholds, through the recognition of civic rights and the extension of suffrage, ushered in the age of mass politics with mass parties and mass election campaigns. For Rokkan, an unbroken tradition of representation, a history of continuous center building, and a Protestant nationalization of territorial culture were the main factors favoring an earlier, more gradual, and stable democratization.

The lowering of the third threshold implied a transition from majoritarian to proportional representation, easing the access of minorities to representation in the legislature. In his view, the pressures for proportional representation were higher in the ethnically and/or religiously heterogeneous countries, and in general in the smaller nations with their greater international dependence.

The introduction of universal (male) suffrage in all Western European countries at the end of World War I and the transition to proportional representation in most of them tended to stabilize the party systems of the 1920s for a long time, in most cases until the 1960s (Rokkan's famous 'freezing' thesis). In Rokkan's view, the party systems of the 1920s reflected older cleavages that had emerged in the earlier processes of state formation and nation-building and became politicized and organized in the process of democratization.

Cleavages are understood as strong and enduring conflicts that tend to polarize a political system. Rokkan distinguished between four or five basic cleavages that emerged at different critical junctures in European history. The *National Revolution* (1789 and after) produced two cleavages, with even older

roots in the early state formation processes and the Reformation:

1. the *center–periphery cleavage:* conflicts between the central nation-building culture and ethnically linguistically distinct subject populations in the peripheries;
2. the *state–church cleavage:* conflicts between the aspirations of the centralizing, standardizing, and mobilizing nation-state and the corporate claims of the church.

Two further cleavages were produced by the *Industrial Revolution* in the nineteenth century:

3. the *land–industry* cleavage: conflicts between the landed interests and the rising class of commercial/industrial entrepreneurs; and
4. the *worker–employer* cleavage: conflicts between owners/employers and tenants/workers.

The class cleavage was overlaid by a fifth cleavage between proletarian internationalism and nation-accepting socialism as a result of the *International Revolution* (1917 and after).

According to Rokkan, the differences between the European party systems largely were produced by the first three cleavages, reflected in the presence or absence of regional, Christian, or agrarian parties. Whereas Christian parties emerged mainly in the religiously mixed and some of the Catholic countries, agrarian parties are found only in Protestant areas. The class cleavage, by contrast, produced working-class parties in every country, but their strength and unity differed greatly due to the socialist–communist split.

State Formation and Nation-Building in Europe

In analyzing the historical development of the different cleavage structures, Rokkan took a decisive step beyond traditional comparative research: he no longer regarded the units of comparison, the nation-states, as given, but rather thematized their development itself. In these later works, Rokkan was influenced greatly by Hirschman's concepts of exit, voice, and loyalty, which he used in his analyses of the development of the nation-state in terms of boundary-building, internal structuring, and system-building.

Rokkan distinguished between four basic processes of loyalty-producing system-building: state formation and nation-building; two processes mainly of boundary-building and two processes of mainly restructuring, the establishing of political citizenship by equalizing the rights to participation and the establishing of social citizenship by redistributing resources and benefits. In the older countries these processes tended to follow each other in time, whereas in the newer countries the problems associated with them often cumulated.

In the European context, according to Rokkan, these processes were influenced by six givens: first, the heritage of the Roman Empire (law and citizenship); second, the tradition of the Germanic kingdoms (legislative/judicial assemblies); third, the crucial role of the supraterritorial Catholic Church; fourth, the growth of a central city belt; fifth, the development of feudal and manorial agrarian structures; and sixth, the emergence of literatures in vernacular languages.

The European world of states and nations emerged from the disintegration of the Western Roman Empire, after centuries of territorial fragmentation and retrenchment, followed by processes of expansion and reorganization. For Rokkan, 'the alphabet and the city decided the fate of Europe' (Rokkan, 1999) in these processes. As a result of various waves of migration, a new 'ethnic-linguistic infrastructure' arose in the Middle Ages. The alphabet made it possible to turn spoken into written standards of communication, and this vernacularization provided a basis for the later nation-building.

The city belt in turn was a decisive factor in center formation and early state building. The revival of trade between the Orient, the Mediterranean, and the North Sea had produced a belt of independent cities from Italy to Flanders. The polycephality of the citystate Europe either delayed state formation (Germany, Italy) or led to confederations (The Netherlands, Switzerland). By contrast, monocephalic city structures conducive to centralized state development formed at the western and later also at the eastern end of the city belt. The rise of Atlantic capitalism, however, brought with it a European division of labor that strengthened the Western states, while the Eastern states largely became incorporated into empires.

The variations in city structure and thus the tripartite division of Europe into a Western Europe of unitary, centralized nation-states, a federalist Central Europe, and an Eastern Europe of multi-ethnic empires constitute the 'west–east axis' in Rokkan's well-known typological–topological model or conceptual map of Europe. It helps to explain the great paradox of European development: that the strongest and most durable systems emerged at the periphery of the city belt and the old Empire.

While the 'west–east axis' defines differences in economic conditions of state formation, the 'south–north axis' denotes differences in cultural conditions of nation building, depending on the geopolitical distance northward from Rome. Rokkan interpreted the Reformation as the first major step in defining territorial nations in Northern Europe, whereas in Catholic Europe the Church remained supraterritorial.

The conditions for successful center-building and territorial consolidation as well as for cultural standardization and identity-building, therefore, varied across Europe in a typical and topological way. The easier these processes of territorial and cultural boundary-building, Rokkan generalized, the more gradual and less violent were the internal restructuring of the nation-states through the establishment of citizenship rights.

Towards the end of his life Rokkan attempted to integrate his comparative studies into a comprehensive model of Europe spanning the entire history of state formation, nation-building, and mass politics in Europe and identifying the crucial variables in the long and complex process that led up to the current constellations of territories, economies, and systems of political alignment. This macro-model remained a sketch exemplifying the nature of most of Rokkan's studies, which were essentially research programs.

Rokkan's Comparative Approach

Rokkan defined the decisive challenge of cross-cultural, cross-societal, and cross-national research as follows: 'We propose to direct our attention to one single, central set of issues: the

possibilities of translating "grand theory" into empirically workable "typologies of macro-settings" for variations in human behaviour, and the consequences of such typologies for decisions on the cultural and the geographical range of comparisons at the level of communities, households, and individuals' (Rokkan, 1970b).

From this fundamental orientation, Rokkan developed a series of basic elements that characterize his comparative approach: the need for context-specific comparisons, the multidimensionality of contexts, the twin concepts of structuring and boundary-building, the dynamics of freezing and unfreezing at critical junctures, and finally the method of retrospective diachronics.

For Rokkan model-building always had to be context-specific: 'No single explanatory or intervening variable can be linked up with a dependent variable in isolation from the context, whether across systems or across stages' (Rokkan, 1999). Because such macro-contexts are comparable only to a certain degree, Rokkan was skeptical of universalizing comparisons and instead preferred region- and period-specific models, particularly in his cleavage model and his conceptual map of Europe.

The macrocontexts are in principle multidimensional, since for Rokkan they always resulted from interactions between three different systems, the political, economic, and cultural systems. Due to their relative autonomy, he started in his macromodel from configurations, rather than hierarchies of factors: 'There is no economic determinism in the model, nor a geopolitical, nor a cultural: in this sense it seeks to combine the traditions of Karl Marx with those of Max Weber and Emile Durkheim.'

While all three systems have a territorial dimension, only the political system is ultimately capable of controlling territory. Territory is a crucial concept in Rokkan's comparative analysis of political systems. It is a starting point for his most basic twin concepts of structuring and boundary-building in the formation of territorial systems. Such systems essentially are structured through the formation of political, economic, and cultural centers and the incorporation of peripheries. Their consolidation presupposes a process of political, economic, and cultural boundary-building which in turn contributes to the emergence of territory-wide cleavages. Center-periphery relations and cleavage structures are the two dimensions that for Rokkan underlay the institutional and organizational structuring of political systems.

With his twin concepts, Rokkan went beyond traditional comparative research that was limited to comparing structures and focused on the formation of systems as a process of structuring and boundary-building. In this historical process critical junctures are crucial. This concept of Rokkan's refers to political, economic, and cultural 'revolutions,' historical events and processes which he used to distinguish between periods: between 'critical junctures' when basic new decisions are taken, structures are 'unfrozen' and boundaries are 'opened,' and periods in which the institutional and organizational structures remain 'frozen' and the boundaries 'closed.' This attempt at periodization underlies Rokkan's basic method of retrospective diachronic analysis which addresses the question: 'given an observed contrast in the values of variables at time t_i, what combinations of variables for earlier phases t_{i-t}, t_{i-2}, and so on, can best account for these differences?' (Rokkan, 1999).

In this way, Rokkan attempted to explain systematically current structural differences between the European societies and polities as arising from their long-term development. In many cases, his efforts to do so took the form of research programs. With his contributions to developing a social science infrastructure, he wished to create a basis for carrying out these programs. In both respects, Rokkan has left us an important legacy.

Roma People

Abstract

The Roma people – formerly often referred to as 'Gypsies' – have a unique history, and a precarious current existence. They are estimated to be about 10 million in Europe, and some 2–3 million elsewhere. Their lives have been characterized by mobility within and between countries, and social marginality. The analysis of Romani language shows evidence of an Indian origin. In Europe the Roma have historically been strongly linked to a variety of occupations of trade and craftsmanship, but unemployment has tended to be high. While twentieth-century socialist regimes in Europe tended to integrate Roma into national economies by varied means, later economic regimes have again left them more often excluded.

In the year 2013, when this article was written, an ugly new tale of abuse, harassment, or persecution of Roma in different countries of Europe seemed to emerge daily. The claim from the Socialist French Interior minister that the Romany way of life was incompatible with French values stood out as did the witch-hunt style kidnapping of (blonde) Romany children from their families in Greece, Poland, and then Ireland; but one story seemed to evoke particularly powerfully the plight of Europe's largest minority.

Three years earlier, in 2010, a 40-year-old Romani beggar – who was a notorious vagrant in the town of Kosice, Slovakia – had been stabbed to death, in a savage 40 s attack, by a Slovak man half his age. Since then the killer had not spent 1 day in custody – originally, and incomprehensibly, charged with battery he had remained free when the charge was increased to murder. He then refused to testify during the preliminary proceedings and maintained his silence during the main trial.

In December 2013, the District Court in the Slovak town of Košice acquitted this non-Romani youth and set him free. The judges based their decision on psychiatric reports that for a fraction of a second, the killer had found himself under the influence of a delusional, psychotic, but temporary, disorder. He had been in a state close to unconsciousness in which his ability to tell right from wrong and his capacity for self-control disappeared and believed that the beggar intended to kill him. The psychiatrists added that they had no reason to think this man suffered from any enduring chronic mental disease or disorder – he should be set free at once.

In Europe one would have to go back to 1930s Germany or in the United States to the precivil war period to find court proceedings so racist and unjust, in which the life of a citizen is held in such contempt. But in 2013, so common are these kinds of events that they barely excite comment outside the online circles of engaged academics.

Who Are 'The Roma'?

The 'Roma' represent a more or less unique case in the history of the modern world. The label 'Roma'– which has largely replaced the former 'Gypsy' is now used to refer to a large globally dispersed 'community of communities' estimated at 10 million in Europe and maybe 2–3 million elsewhere, that, in anthropological terms, defies simple definition. Indeed, despite the fact that when 'Roma' travel from one country to another they have little difficulty recognizing other 'Roma' as 'fellow Roma,' but invariably determine that these are 'not our sort of Roma,' it makes no sense politically, sociologically, or anthropologically to talk of 'The Roma' as a single entity. In the absence of a Romany state or state-like institutions anywhere in the world, the homogenizing forces that produce national (or ethnic) type identities, 'The Roma' remain a remarkable exception to the iron laws of modern development that predicate cultural persistence on robust political bases. And yet Romany communities reproduce themselves while living both among a politically dominant majority and dispersed among such. How this persistence of Romany social forms is achieved remains a true puzzle for modern social science.

Scholarly debate on Romany identity and community can be broadly divided into two main positions. On the one hand we find scholars who adopt an 'ethnic origin of nations' approach (as in the work of Anthony Smith) and see 'The Roma' today as an ethnic diaspora united by the current or historical use of dialects of the unitary Romany language. For these scholars if Roma see themselves as a less well-defined group than, say, Jews or Armenians, this is more to do with aleatory conditions of history than their capacity to form a nation in the modern sense of the term. Such scholars will talk of the Indian ancestry not just of the language, Romani, but also of the people themselves. On the other hand we find scholars influenced by the institutional constructivism of Benedict Anderson as well as by anthropological approaches to ethnicity and nationalism. They see nations and ethnicities as the product of historically contingent, modern, political arrangements and refuse to project ethnic type identities back into the premodern world. These scholars, while being more or less interested in the historical connections among Romany populations of the world today, reject talk of diaspora, are more interested in diverse ancestral populations (in the plural) than in finding one root-stock and focus on the socio and economic niche that has enabled Romany persistence in Europe in particular since the first fourteenth-century reports of speakers of Romany were published. As a consequence, the former group of scholars tend (at least when being consistent) to exclude from their definition of Roma, all those populations like the Irish Travelers, the German Jenische, and others who

appear to have no historical connection with speakers of Romany. There remains, however, plenty of room for ambiguity in such tidying up. Do the 'Boyash (aka Baiesi)' who speak neither Romani nor use Romani terms in their dialects of Romanian or English, but whose way of life is distinctively 'Gypsy-like,' count as 'Roma'? For what it is worth, for the most part Baiesi deny their historical connection with 'Roma.'

From a political point of view, Romany diversity poses a huge challenge both for activists who would seek to build the European equivalent of a civil rights movement and for governments or transnational institutions like the EU or Council of Europe that seek 'legitimate partners' for dialogue and community leadership. While activists often seek to impose a phantasmagoric nineteenth-century vision of a unitary Romany culture forged in the 'Indic cradle of civilization,' the political institutions have created an equally phantasmagoric 'community of Roma' with self-appointed representatives of which they can then deal 'democratically and transparently.' From the point of view of social science, however, the diversity of Romany social forms alongside the undoubted familial resemblance of different Romany populations offers a unique chance to study the sources of social and cultural diversity in a nonnational context. It might also be noted that whatever the source of Romany adaptiveness, the spread of these communities over the world and their persistence through waves of persecution and assimilation suggests a resilient social form.

Language Histories – Romani

Romani is the name commonly used in scholarly literature for the language of the Rom. It is the (feminine singular) adjective derived from the collective noun that self-designates speakers of Romany, rom (the now pc Roma is a late interpellation from some western dialects (NB with a hacek on the r)), as in the phrase *romani chib (hacek on c too)*. Colloquially, speakers of Romani will refer to their language as *romanes* (literally 'in the Romany way') but in the academic literature the term Romani has stuck. It is the only Indo-Aryan language that is spoken exclusively in Europe (and among migrant populations in the New World). As an Indic language it is also unique in having a European ('Balkan') syntax.

The earliest source on Romani is a short list of 13 sentences published as *Egipt speche*, with English translation, in 1542 by Andrew Borde, but it was not until the late eighteenth century that an international circle of scholars engaged in a correspondence that led to Professor Johann Rüdigger of Halle publishing, in 1777, the first systematic comparison of Romany spoken in Europe with 'Hindustani' that established the Indic origin of this language. Because of the absence of written sources the history of the language can only be constructed speculatively using the principles and procedures of historical linguistics. Although the eighteenth-century scholars were pioneering autodidacts, modern historical linguistics has confirmed in great detail their initial insights. In the most substantial examination of the topic, Yaron Matras of Manchester University, has concluded that proto-Romani – the language that was spoken in India – before any contact with middle eastern languages like Persian – was something of an Indian hybrid language, a central Indian dialect that at some time in the first millennium CE underwent a convergence with northern Indic languages. As Matras (2002) stresses throughout his work, Romani has always been a language in contact, and the shared traces of contact languages found in all modern version of Romani (in particular Persian and even more importantly Greek loan words) provide compelling evidence of the habitat of ancestral speakers of the language. Extending our understanding of the linguistic data to population history is, however, fraught with difficulty. Does the presence of many Greek loan words in Romani reflect the 'relatively recent' contact or a more powerful (possibly more enduring?) social contact between speakers of Greek (possibly in Asia Minor) and Romani speakers?

Though Romani is a language in contact it is not – as some have sometimes speculated – a contact language in the sense that Yiddish arose as an ethnolect of Jews living in the Rhine area which then spread in particular to eastern Europe and was subsequently spoken from Hamburg through Prague and Krakow to Alexandria in Egypt. In accordance with its origin, Yiddish shares most of its lexicon and morpho-Syntax with (Southwestern Franconian varieties of) German. Romani, with its significant Indic lexicon and Indic inflections, is quite a different case.

However, extrapolating social history from linguistic history is no simple matter. Speaking rather generally, the existence of a number of dialect groups among Romani speakers in Europe demonstrates a fairly clear pattern of demographic division. The linguistic map today demonstrates a distinction between Balkan (e.g., Arli or Xoraxane), Vlax (originating from Transylvania and adjoining regions, e.g., Lovari, Kelderas), Central (of the former Hapsburg lands, e.g., the 'Romungro' dialect spoken today in Slovakia and western Romania), Northeast (Baltic–North Russian, e.g., Polska and Latvian Romany), and Northwest (German–Scandinavian, e.g., Sinti and Finnish Romany) dialects. To a large extent this map reflects early modern political boundaries. But the more outlandish claims of an earlier generation of amateur linguists and philologists, like the Hungarian Jozsef Vekerdi – that for instance Romany social history (nomadism, supposed aversion to agriculture, etc.) could be traced in the lexical retentions from Indo-Aryan – are now wholeheartedly rejected by modern linguistics.

Because the linguistic evidence is all we have to go on in reconstructing Romany population histories, considerable effort has been put in by a small group of population geneticists to try and trace 'origins' of some of today's Romany speakers. At considerable public expense they have proven nothing more than that Romany has been passed on within families over the past 60 or 70 generations, and that, therefore, there is clear evidence of an Indic origin of some of the ancestral speakers of Romany. This work – complete with its overblown attempts to date demographic events and frequent downplaying of profound founder effects in the data – represents a weak tail-end of the popular field of population genetics. Far more interesting and significant has been work in comparative linguistics that has shown the historical links of Romani and other Indic languages spoken in the middle east – Domari in particular. Thanks to this work – most of it carried out under Yaron Matras' leadership – it is now clear that Romany is but one of a group of Indic languages that have been

spoken outside of South Asia in the past 1000 years. Of perhaps greatest interest is the possibility that, linguistically, Romani and Domari separated long before speakers of either language migrated west, but that speakers of both languages may have occupied parallel occupational and social niches in the host societies of the near and middle east producing various parallel evolutions in the languages.

Of today's estimated 9–10 million 'Roma' in Europe, some 3.5 million or more speak Romany. The younger generation of these speakers is currently in the process of creating a loose international dialect and standard written form based on electronic communication. Though there have been self-serving attempts by some self-appointed 'experts' to impose a uniform standardized Romany it appears that the sheer mass creativity unleashed by the Internet will overwhelm these academic replays of nineteenth century 'language renewal programs.'

In some regions of Europe, especially the western margins (Britain, the Iberian peninsula, Scandinavia), Romani speaking communities have given up their language in favor of the majority language, but have retained some Romani-derived vocabulary as an in-group code. Such codes, for instance Angloromani (Britain), Caló (Spain), or Rommani (Scandinavia) are usually referred to as *Para*-Romani varieties. Probably a majority of those identified as Gypsies in Europe today are more or less monolingual speakers of their national tongue, like the large Gitano population in Spain and the 'Hungarian Gypsies' within modern Hungarian borders. The extent to which they identify with Romany speakers is particularly labile and open to entrepreneurial innovation.

Occupational Histories – The Legacies of Infamy

Today we find individuals who self-identify as Rom in all walks of life from Presidential counselors, through the legal and medical professions to political activists and academics, actors, classical and jazz musicians, writers, poets and journalists, as well as the whole range of manual and technically skilled professions. There is also a strata of Rom who are actively involved in various entrepreneurial activities from animal markets through second hand cars to antiques and real estate. However, the vast majority of people who either self-identify as Roma or are identified as 'Gypsy' by the majority society are in occasional, manual, or other unskilled employment. Across eastern Europe where rates of employment of unskilled manual labor are very low (compared with western Europe) and especially where economic reform has stagnated (Hungary, Slovakia, Bosnia above all) massive unemployment characterizes Romany communities. In more dynamic economies, like that of Romania, migration to the labor hungry markets of Italy and Spain has provided new demand for low-paid labor.

Historically, it is most unlikely that Romany communities ever adopted a single economic niche. But the range of their economic activities does seem to have been generally constrained by a combination of: preadaptation to the provision of services to the agricultural or urban economy; legal and practical restrictions on residence/land-ownership (no Romany communities have benefited from the various land reforms of the past century in eastern Europe, not even the most recent post-1990 one); and, finally a political culture that promoted independence over security. Almost certainly, however, in the distant as in the recent past Romany persistence relied upon enormous flexibility in economic strategy – a willingness to combine day-laboring with begging with trade with artistic performance, as opportunities presented themselves. Through history such flexibility would seem to be essential for survival on the social margins.

In terms of historical evidence the German speaking states of the eighteenth century provide the best documentary evidence for premodern Romany economies. All those people officially labeled *Zigeuner* were part of a vast swathe of population below the three official Estates, which 'wandered about the country,' as the distinctly pejorative German verb *herumziehen* had it. The *Zigeuner* were thus just one part of a broader but inherently suspicious group that was more or less socially alien to local society. Boundaries between the *Zigeuner* and other 'masterless men' were weak. Among these footloose people were all those who dealt with carcasses and the polluting processes of bodily decay as well those who put their persons on display in public, like actors, puppeteers, musicians and prostitutes, people whose very touch could pollute honorable persons. This *unterschicht* ranked in its numbers all those who supported themselves precariously through the peddling of trade and services, the makers of shingle, sulfur-matches, spindles, pick-hammers, blow-pipes and tinder, spoons, baskets, sieves, boxes, and powder-horns, repairers of coffee-grinders, book-binders, knife- and scissor-grinders, pitch-burners, itinerant traders in Frankincense, coopers, hawkers of lace, pewter, heels, rope, southern fruits, hats, pots, leather, vegetables, and tobacco. Certain specialisms recur in the records in conjunction with the label *Zigeuner*, some of which involve metal work, like the pot-binders (who repaired shattered pots with wire), buckle-makers, producers of dough-trays, grills, combs, wool-combs, drills and book-clasp makers; hosiery, broom and brush-makers, as well as the occasional 'stone-breaker' also make an appearance linked to the label *Zigeuner*.

In a fashion that is now quite hard to fathom, there was for eighteenth and even nineteenth century society something inherently suspicious and dubious about the providers of such a chaotic array of services and goods. They were a 'rabble of masterless men,' (*herrenloses Gesindel)* on edge of the *Gaunertum*, 'the world of rogues and vagrants.' They were involved an unsettled and wandering (*nichtssesshafte*) existence, and this, in and of itself, rendered a person infamous or dishonorable to a greater or lesser extent because it placed them outside of the hierarchy that was the basis of social life. Moreover, while the actor or musician was explicitly infamous for putting himself on display, the destitute peddler-beggar was, in the words of a French historian, Laurence Fontaine, "ultimately selling himself and all that his words – spoken or sung – could stir in the imagination of his listeners" and, as such, existed only a step away from his infamous self-exposing cousin.

In the poorer region of eastern Europe, where the great mass of European Rom have lived we can presume that income from such unsettled sources played only a minor role in most families' survival. Almost certainly then as in the twentieth century enduring ties to local farming families would have provided sufficient day laboring to get through the year. But here too this placed the Gypsies at the bottom of the social

order since the day laborer was the lowest of the low – even more worthless than the serf who at least had a permanent master.

In the context of this quasi-feudal social order that endured into the nineteenth century, one occupation is particularly worthy of mention – musicianship. In the Hapsburg lands in particular but also in premodern Spain, the provision of music provided Romany families with one means to transcend their inherited social status. Then, as today, the ability to conjure magic from singing or playing an instrument was the most promising route to transcending outcaste status for the socially marginal. In some cases – Hungary after the defeat of the 1848 revolution in particular, but twentieth century Spain provides another example – Romany musicians came to be associated with 'the national cause' and acquired an enduring elevation in social status. In the communist period, for example, Hungarian Gypsy musicians who traveled abroad in 'Gypsy Orchestras' saw themselves as outstanding ambassadors for their country. In post-cold war Europe a few bands of Romany musicians have also been able to plug into the world music scene with similarly transformative impact.

The greatest single transformation in the economic niche of Romany communities in Europe has, however, been the enforced employment programs of the communist regimes from 1947 to 1989. Across eastern Europe and the former Soviet Union the vast majority of those identified by the state as 'Gypsies' were both enabled and compelled to take up full time employment in 'socialist wage labor.' By the 1980s over 90% of Romany men and two thirds of the women were in full-time employment across the region. The economic policy drive to full employment was also the central plank in a social campaign to assimilate the Gypsy minority. On this front, all the evidence suggests, the regimes were less effective. Even under communist rule, Gypsies were given the worst paid, the dirtiest, the least attractive, and the least secure jobs and the poverty of their material conditions was reproduced despite all the egalitarian rhetoric of the 'workers' states. The more robust Romany communities also sought out areas of employment where whole families could work together and not under the controlling eye of a foreman – for instance in town sweeping (carried out in groups unlike the individualized rota of a hospital cleaner) or in nautical scrap iron yards. In other areas of employment, Roma benefitted from socialist planned economics. Over 20 000 Romany musicians were officially registered in Hungary in the late 1980s with several 1000 playing fixed slots in restaurants in the capital city. All these artificially created employment opportunities disappeared with the system change. Factories closed or were replaced by machines, for instance, several (like 10) unskilled laborers with one machine operated by a single semiskilled mechanic. And even in music fashions changed. By 2003, with all employment restrictions lifted, there were barely few score 'Gypsy musicians' making their living in Budapest's restaurants.

Although a significant part of eastern European Romany populations have benefited from the system change a majority have found themselves increasingly economically and socially isolated. The mixed society of 'masterless men' continued in one form or another through to 1989. But with the radical change in agriculture and the ending of subsidies to live in cities many Roma have found themselves driven out to villages from which the majority population has fled. For the first time in Europe we are seeing the emergence of *de facto* ethnic ghettos entirely cut off from the outside world. The demographic, social, and economic consequences of these developments have yet to be felt.

Political Histories

Narratives of unending victimhood have come to dominate activist-inspired 'histories' of the Romany people. In part inspired by the paucity of sources on Romany history (for much of the past 600 years we have only the occasional judicial record), the early history of Romany communities is often written as a progression from mistrustful welcome, through antagonism to repression and expulsion. In such accounts, centuries of discrimination reached their climax in the Second World War when the Nazis and their allies murdered well over 100 000 Roma (half a million according to activist histories). Communism then imposed a new version of repression in the form of assimilationist policies. According to such accounts it is only now in the twenty-first century that Roma may be able to stand up for their rights and demand the recognition that they deserve.

This kind of simplistic narrative is, of course, not wholly false but there is now substantial historical work showing how one-sided and misleading the miserablist account is. Most broadly speaking, the very paucity of data about Romany populations and even the repeated expulsion orders (repeated because unenforced) may be taken as evidence for a peaceful and, within the frame discussed above, tolerant coexistence, indeed symbiosis, of Romany groups with their host populations for most of the past 600 years. The work of Thomas Fricke and Ulrich Opfermann demonstrates a far more complex picture of mutual dependence, intermarriage, and flexible identities at least within the '*unterschicht*' of premodern society. Because the administrative term '*Zigeuner*' did not truly refer to an ethnic group in the modern sense of the term (there were no such things in eighteenth-century Europe) but rather to a (mostly inherited) life-style and because even Romany speaking *Zigeuner* were always bilingual in German, it was perfectly possible for people branded as *Zigeuner* to claim as did one woman interrogated in Stuttgart in 1781 that "now we are no longer Gypsies [since] we have been given *schutz* (protection)" that is to say entered a formal relationship of subordination with a master. She freely admitted that she spoke 'the Gypsy language' since her parents had used this when she was a child, but since becoming a resident of a community she and her family were now allowed to hawk their goods (porcelain from the Duke's factories) throughout the country and so no longer counted as *Zigeuner*. Or, as another Romany speaking man claimed some generations earlier, "I should not be seen as a Gypsy, rather a Trumpeter of the Kaiser" (Opfermann) – whatever these people's familial identifications as speakers of Romany, their labeling by the state was far less rigid than a twentieth century 'ethnic' framework would suggest.

More broadly, historical work has demonstrated that there has been no single 'European' history of Romany populations. A Foucaultian approach would suggest that a deviant population,

like itinerant Romany speakers, would have universally become a prime target of the modern surveillance state. In fact, as Leo Lucassen has demonstrated variations in the institutional configurations of modern states has profoundly affected the way Romany populations are treated by officialdom. There was a profound difference between the experience of Romany speakers and Gypsies in Great Britain, where after 1660 issues of vagrancy gradually became municipal and not national issues and Germany where from the eighteenth through the twentieth century there was a gradual criminalization of 'vagrancy.' Later, the way the police in Germany became significantly involved in administering welfare and public health issues also put them on the frontline in dealing with problems of poverty in the new cities of the Reich. As a result by the early twentieth century the German police had in place a whole system of surveillance of the 'hard to identify' populations – a system that the Nazified Criminal Police, or *Kripo*, put to extensive use in the 1940s when determining who was deported from Germany.

Communist policies toward the Romany populations of eastern Europe displayed a particularly radical form of what we might call the enlightenment approach first pioneered by the Hapsburg ruler, Maria Tereza, in the late eighteenth century. Being a 'Gypsy' was treated as a lifestyle and it was assumed that Romany cultural and linguistic practices were superficial traits that would be abandoned once full social integration was on offer. Postcommunist, democratic polities have, by and large, taken the opposite stance – stressing the distinct cultural and linguistic practices of Romany communities while condemning a large part of the Romany population to ever greater economic and social marginalization. Under the name of respect for multicultural difference, radical new systems of segregation are being invented in parts of Europe today.

Cultural Histories

The persistence of Romany sociocultural forms represents a truly fascinating sociological puzzle. Because Roma have not historically formed territorial settlements, all 'Roma' communities live in the middle of and dispersed among majority populations; they are always more or less familiar, indeed intimate, with the cultural world around them – always speaking the language/s of the dominant community; and yet they reproduce their 'communities' with apparent ease, retaining a sense of themselves as 'Rom,' and they do so without shared religion, without any form of ritual or political leadership, without overarching or underpinning political organization and without recourse to identity strategies rooted in transnational or diasporic rhetoric. In other words, they challenge that casual assumption promoted by the experience of growing up in well-homogenized nation-states that cultural and social continuity is predicated on the ability of states politically and institutionally to ground cultural forms. How Roma communities 'get by' has not yet been properly explained by any of the scholarly disciplines that deal with Romany sociality.

The diversity of Romany socialities – understandings of what constitutes a social order – has driven those scholars familiar with the inner life-world of Romany communities to reject the whole idea of there being a single 'Romany culture.' Patrick Williams and I recently coedited a text entitled *Des Tsiganes en Europe* (Gypsies in Europe – i.e., *not* The Gypsies of Europe) in order to stress this point. And yet there are continuities. Living in communities that exist within another culture and do so under conditions of dispersal, Roma use strategies of visibility and invisibility vis-à-vis the 'host' society, with a strong preference – as Patrick Williams (2003) has long stressed – for rendering the socially valuable invisible to the non-Rom world. It is perhaps for this reason that Rom are often keen to conceal their kinship ties in official papers – as if aware that this is the one area of social life where the authorities might take hold of them.

Another common feature of Romany strategy is that in the absence of any overarching social order, the atom of Romany sociality becomes the reproducing family – that is to say the network of kin within whom it is possible to reproduce over time. It is striking that words that are used by outsiders as if ethnonyms are, in a colloquial use, nothing of the sort. When German 'Sinti' talk of their community as 'amare sinte' the correct translation into English is not 'our kind of sinte' but 'our relatives.' Of course, in the national political arena German Romany activists are perfectly capable of adopting (in the German language) the malapropism of 'Die Sinti' as if the term named a people but, in a curious way, this very gesture also undermines their local credence as indigenous leaders.

Such strategies aside, how Roma accomplish the core business of social reproduction varies significantly from place to place and time to time, at least if the ethnographers are to be believed. Among Spanish Gitanos described by Paloma Gay y Blasco (1999, 2011), for instance, Romany sociality is constructed in the performance of a gendered identity by each individual Gitano and Gitana. Rigidly enforced by excommunication, the 'laws' of the community are not codified other than in the embodied gendered performance of each Gitano individual. Among the 'Manouches' of France – and probably 'the Sinte' of Piedmont and beyond the social is constructed around each individual's respect for his or her own dead and the knowledge that others have of this. In Patrick Williams' account, Manouches transcend the uncivilized, almost barbaric lack of restraint they observe among the Gaźos (non-Gypsies) by systematic but silent acts of renunciation. These unspoken acts of respect for the dead create, invisibly, an extraordinary moral edifice untouchable by the outside world. Among the Vlach Rom of Hungary, in the socialist period at least, sociality centered on the creation of a world of brotherhood. In particular in alcohol fuelled musical celebrations a short lived, single sexed community of Romani-ness provided an image of a social order that would transcend all the importune demands of a civilizing social order. Among the Gabor and Cortorari Rom of Romania the social order seems constructed around the transmission of valuable kula-type wealth in the form of putatively ancient beakers which contain familial potency. I could go on – in each of these Romany communities social value is constructed and its transmission through time takes place in significantly divergent ways. And yet, when these Rom come to meet up – in a French hospital Accident and Emergency department or a Spanish agricultural labor market, let us say – they recognize each other as 'Rom' but 'Rom of another kind' (*streina rom*). How such a sense of commonality may yet ground new *trans*-communal identity strategies – through

intermarriage, through social networking fora, through joint political activity – remains to be seen.

Certainly, ethnographic studies of the postcommunist period demonstrate how fluid apparently fixed arrangements can be. Former musician families in Hungary who had lost their old secure employment in the late 1980s were rapidly able to convert their social capital, working as waiters for shorter or longer periods in their former restaurants and then moving into commercial work in neighboring Austria. They were also able to generate new political capital in the postcommunist system of ethnic representation. As Romany cultural identity was being revived as a political value capital by the ethnicizing post-communist regime so these musicians, whose grandparents had begun an apparently irreversible trend toward cultural assimilation into the majority population, suddenly revived their cultural 'romaniness.' This itself led to new forms of social interaction among 'groups' of Roma who had, in the communist period, tended to keep to themselves.

Such shifts in the social value and significance of Romany ethnic identity can be found across eastern Europe in the past 20 years as two young Hungarian ethnographers, Cecilia Kovai and Kata Horvath have demonstrated. In the communist past although the Gypsy/non-Gypsy distinction provided the basis of all social interaction between members of these two categories in villages and small towns, because of the rhetoric of assimilation this fact was *never named* and so no one was ever called 'a Gypsy' to their face. This meant that the Gypsies lived under a constant pressure, that they should not behave in such a way as would force someone to call them 'a Gypsy.' They lived with the false promise that if they became educated, acquired wealth, lived like 'normal people' (read 'peasants' or 'workers') then they would be treated as such. But the promise was illusory. Now, however, thanks to economic, demographic, and, above all, political changes, the promise of assimilation has been taken back and 'the Gypsy' is constantly named and the Gypsies more or less happily bring their 'Gypsiness' to the public space. In consequence, the majority feels (quite unreasonably in many respects) that they are engaged in a battle for territory with this newly named presence, 'the Gypsies,' who are taking over their institutions (the school, the bars, economic life). They feel 'their' space is constantly encroached upon by this previously unnameable but ever present social force.

This shift, and many others in the stagnating polities of Hungary, Bulgaria, Slovakia, and the Czech Republic in particular have contributed to the rise of threatening and very innovative political forms that – for the first time in Europe – target 'The Gypsies' as the main social menace and the dominant social problem of our time. Political parties like the Hungarian *Jobbik* or Bulgarian *Attaka* or Slovak '*People's Party – our Slovakia*' represent the most innovative and dangerous forms of this new populist 'anti-Gypsyism.'

Roma People: Discrimination and Social Work Practice

Špela Humljan Urh, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article presents the history, origin, common stereotypes, and current ethnic reality of the Roma people. The two most explicit myths (nomadism and homogeneity) are challenged. The Roma are recognized to be one of the most marginalized ethnic groups worldwide. Throughout their history, they have faced negative social attitudes among the dominant society, which is one of the strongest factors contributing to their marginality. Due to their ethnicity, Roma people face discrimination more often and in more spheres of everyday life than non-Roma. Roma children and Roma women, especially, face multiple discriminations. Antiracist social work theory provides social workers with knowledge on how to work with marginalized communities.

Introduction

This article presents the history, origins, common stereotypes, and current ethnic reality of the Roma people. The two most explicit myths (nomadism and homogeneity) are challenged. Roma people, numbering from 10 to 15 million in Europe, are recognized to be one of the most marginalized ethnic groups worldwide. Throughout their history, they have faced negative social attitudes from the dominant society. This is one of the strongest factors contributing to their marginality. Schooling, employment, housing, political representation, and negative media representation are the most criticized areas by those advocating on behalf of Roma people and their issues. In this article, special concern is placed on the two most oppressed groups of Roma ethnicity – Roma children and Roma women. One-half of all Roma in Europe are school children with only a small proportion of them being included in formal education. However, those in school often face different forms of discrimination like minimalization of their abilities and ethnic segregation in 'special' schools. Roma women, on the other hand, often experience double discrimination: sexual discrimination in their own community as well as ethnic discrimination as members of the Roma minority in the wider community. Special emphasis is placed to the antiracist social work when it comes to reacting to violence, aggression, and conflict behavior in Roma families. In such cases, ethnic pathologizing occurs when social workers attribute such behavior to their 'Romani nature.' Many examples of the social workers' reactions reveal racism in their practice. At the end, a clear stance to integration along antiracist principles (Dominelli, 1988; Jones, 2002; Thompson, 2001) in social work education is made. The author also encourages future social workers, especially members of Roma ethnic groups, to follow an emancipatory research approach.

Roma, Gypsies, Travellers – Who Are They?

The Origin of the Roma

Some Gypsies prefer to be called Roma (meaning 'men' in the Romani language, singular 'Rom' and adjective 'Romani'). Others prefer to be called 'Gypsies' in the official language of the country (e.g., Tzigany, Cigan, and Zigeuner). However, in some countries, the term 'Gypsy' has a pejorative connotation. It usually serves as a synonym for a thief, dirt, and untidiness; also the verb ciganiti in Slovenian means to rip somebody off or to cheat (Štrukelj, 2004: p. 66). However, the word Roma was accepted at the first Roma World Congress on 8 April 1971, in London, as a polite expression for members of the Roma minority. The term 'Gypsy' also refers to Irish Travellers (also called tinkers, itinerants). However, they do not share the same origins as Roma – the Roma originate from India, but Irish Travellers are recognized as an ethnic minority who separated from the settled Irish community. Despite their different origins, both minority groups share many common experiences of prejudice, exclusion, and marginalization (Hayes and Acton, 2007).

Soon after the Roma arrived in Europe, many authors began to write about them, speculating about their origin, and describing their cultural characteristics. Many myths were then constructed about their origin and migratory routes until the linguist A. Frederich Pott scientifically studied the Romani language and explained that the homeland of the Romani people was India, more precisely from the Punjab region in northwestern India. According to Hancock (1988: p. 183), "it has been the Gypsy language, or rather the study of its fragmented dialects, more than any other single factor which has led to the general acceptance of an Indian origin for its speakers."

They emigrated probably because of "repeated incursions by Islamic warriors" (Barany, 2002: p. 9) in the sixth century and reached Europe in the fourteenth century (Barany, 2002; Hancock, 1988, 1991; Matras, 2000, 2002). As noted by Matras (2000: p. 34), "migration forms a repetitive pattern throughout Romani history." Today, many have settled and a nomadic life for Roma people is rare. However, many migrate due to poverty and persecution and seek asylum in other countries. In the past, Romani people were subjected to persecution and expulsion, leading them to leave their places of residence. Their migratory movements continue nowadays as a result of political and economic circumstances.

Ethnic Statistics of Roma

There are no unified statistics on how many Roma live around the world. The existing statistics are most often being based on informal estimates of nongovernmental organizations in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28080-X

individual countries. European Commission estimates there are 10–12 million Roma in Europe. A variety of ethnic groups are covered by the label 'Gypsies: Cigany (Hungarian), Cyganie (Polish), Zigeuner (German), Zigenare (Swedish), Čigonai (Lithuanian), Tigani (Romanian), Zingari (Italian), Tsigane (French), Gitano (Spanish), and Cigani (Slovenian, Croatian, and Serbian).' They recognize divisions among themselves based on territorial, cultural, and dialectal differences. There are five main Roma subgroups; however, there are also internal differentiations based on the various crafts that they practice (or have practiced in the past) (Hancock, 2001; Matras, 2002).

Romani Language

Matras (2002: p. 238) states that the Romani language is primarily an oral language. The use of the Romani dialects (around 600) is generally limited to members of extended Romani families and it is estimated that the majority of adult Roma are bilingual (Matras, 2002: p. 238). Also, the Romani language serves as a symbol for the separation of Romani and Gadže (a specific term regularly used by the Roma to refer to those who do not belong to their group, also non-Romani) and as central criterion for group membership (Matras, 2002). A Romani language can be characterized as an ethnic language, maintaining a social distance between Romani and non-Romani people. Also Para-Romani languages (Matras, 2002: pp. 242–249) have gained ground – a mixture of Romani words and words belonging to the dominant majority. Thus, rather than speaking about one, unified Romani language (romani čhib), one speaks about the Spanish Romani, Hungarian Romani, Czech Romani languages, and so on.

Common Myths about the Roma

One of the most common myths about Roma is that they are nomadic people. Yet, a nomadic life was not always their free choice, but a mechanism of survival in a social environment made hostile by the dominant society in a certain local area (after the first emigration from India). Constant threats and not owning land themselves forced Romani people to move. In Western countries, Roma have also practiced commercial nomadism, but this has not been only a Romani way of life. Additionally, in Eastern Europe, Roma were pressurized into accepting a sedentary way of life. Forced settlement was (and still is) recognized as a main political measure applied to Gypsies. As a consequence, a majority of Roma in these parts of Europe is sedentary and nomadism is rare.

Yaron Matras (2000) highlights the distinction between Roma, Gypsies, and Travellers, which are often used as synonyms, assuming an inherent link between these groups. Associating Romani minorities with traveling groups has its roots partly in the traditional romantic stereotype of 'the traveling Gypsies.' But in the context of European migrations, the perception of their migration as traditional nomadism fails to acknowledge that they occurred as a consequence of political circumstances. Nowadays, migrations should not be confused with nomadism. In contrast to the general perception and image of 'nomadic Gypsies,' Matras (2000: p. 33) states that very few Roma are genuinely nomadic in the sense of lacking any permanent dwelling. There are Roma who have a permanent residence and are engaged in itinerant occupations, many travel seasonally to join their extended families, or due to international open-market trade activities.

Another common myth about Roma is they are a homogeneous people, constituting one people with a number of fixed characteristics. Traditionally, it was believed that Roma people have a specific 'Gypsy nature,' which makes them more aggressive or criminally active (Barany, 2002; Belton, 2005; Macura-Milovanović, 2006; Okely, 1994; Schuringa, 2005; Stewart, 1997). These ideas, which imply racist views, have played a prominent role in defining Gypsy identity since the end of the nineteenth century among many scholars. Belton (2005), for example, opposes these ideas and seeks answers in research that show that Roma people are composed of diverse populations that have both nomadic and sedentary ways of life, different dialects, religious practices, occupations, and nationalities. The diversity of Gypsy people is also one of the contributing reasons for an unclear answer to the question of what the Romani identity really is (Barany, 2002; Belton, 2005). What is more, Szuhay (1995: p. 111) believes that who falls into which category is more a political decision than a scientific one.

Marginalized Ethnic Community

The Roma are exposed to multidimensional marginality in everyday life. They are a "transnational, non-territorially based people who do not have a 'home state' to provide a haven or extend protection to them" (Barany, 2002: p. 2). In comparison to other ethnic groups, who share a similar position and experiences of marginality (Kurds and Jews), the situation of the Roma is exceptional and far more comprehensive (Barany, 2002). They came to Europe about seven centuries ago but, despite many changes in the continent's political systems, their position remains politically, socially, culturally, and economically marginalized.

The Roma community is historically recognized as one of the most oppressed and excluded ethnic groups in Europe. Throughout their history, they have faced negative social attitudes among the dominant society, which is one of the strongest factors contributing to their marginality. Roma peoples' development was systematically prohibited or constrained by the societies in which they had settled through the pursuit of assimilation strategies that oppressed them and inhibited their development. Such an attitude to Roma people was especially typical in the territory of the former Austro-Hungarian monarchy during the period of the rule of Maria Theresa and Joseph II, when the Romani language, culture, and history were denigrated and excluded (Barany, 2002; Guy, 1998; Klopčič, 2007; Štrukelj, 2004; Zimmermann, 1999).

In countries under communist regimes (Eastern European countries), hostility toward Roma people was covert. Today, in many countries they experience the denial of their formal and legal rights, as well as overt and covert, intentional and unintentional racism. Several international reports by the European Roma Rights Centre (ERRC), Open Society Reports

(OSI, 2001, 2002), and many smaller research studies from the countries where Roma people live, show that their social position is still worse than that of the majority population. This is evident in cases of mass structural unemployment of Roma people (in all European countries the level exceeds 50% of unemployment of Roma people), minimal educational standards for Roma children in schools, their absence (and silence) in the political sphere, negative media representation of Roma minorities, dehumanizing attitudes of social and health personnel, and social avoidance and ignorance among the majority population (for more, see ERRC web page; also Barany, 2002; Fonseca, 1995; Varsa, 2005).

Two of the most excluded social groups are Roma children and women. Being determined by their age and their gender, respectively, alongside their ethnicity, they represent two of the most vulnerable groups in society. The Roma ethnic minority group is usually discussed in general terms without a mention of gender and age differences. Roma women are a particularly invisible part of the Roma community. Their specific experiences in the public and private spheres remain hidden, with the resulting gender-insensitive practices including in social work contributing to the further discrimination of Roma women.

Roma Children

The Roma are a young population regardless of which society they live within. One-half of all Roma in Europe are school children with only a small proportion of them being included in formal education (Macura-Milovanović, 2006; OSI, 2001, 2002; Peček and Lesar, 2006). Typically, the percentage of the Roma children enrolled in primary schools tends to be low, and the rates of repeating a grade and dropping out are high. Additionally, the participation rate in secondary school programs is low.

One form of the most blatant discrimination against the Roma in education is the segregation of Roma children in special schools for intellectually impaired children (OSI, 2001, 2002; Zaviršek, 2001; Zaviršek and Urh, 2005). There is an evident disproportion, with the share of Roma children attending special schools being even higher in materially more underprivileged Roma settlements. Such disproportions can be found in all European countries where the Roma live. In some of these places, e.g., Germany and Hungary, these special schools are called 'Gypsy schools' (OSI, 2001, 2002). The children's poverty and the ethnicity rather than their potentially low individual intellectual abilities are being the two most common arguments for systematically directing them into special schools and justify 'special' treatment, segregation, and institutionalization. Roma culture is often pathologized and functions as a projection screen for everything deviant, undesired, and unvalued in the dominant culture. Ignorance, misunderstanding, and disrespect of cultural realities often result in the exclusion of Roma children from the system of regular education. Similar cases have also been known in the United States in relation to children of African-American origin (Harry and Klinger, 2006), indigenous people (Haig-Brown, 1988), and other ethnic groups (Devore and Schlesinger, 1999; Eriksen, 2002; Laird, 2008).

According to Thomas H. Eriksen (2002: p. 25), prejudices created and maintained by society in relation to members of ethnic minorities include several mechanisms that maintain the dominant position of the majority society. One of these is the stereotypes that function as 'self-fulfilling prophecies' that constrain, inhibit, or stunt the intellectual development of members of an ethnic minority group by systematically telling them that they are inferior. This is illustrated by the following examples gained through the authors' research:

"The Roma children have low abilities in mathematics" (statement by an expert worker when sending a Roma child to a special school; Zaviršek and Urh, 2005).

"Roma children obstruct classes and impede normal work" (stated by a teacher when justifying a separated school section for Roma children in a regular primary school; Krek, 2005).

"It would be better if the Roma learn to draw as they will never learn to write anyway" (stated by a teacher in the first grade of a primary school while teaching writing; personal communication, March 2005).

Also, a pediatrician tried to persuade a Roma mother during her daughter's systemic medical checkup conducted before starting school to enroll her daughter in a special school where her experience of schooling would supposedly be easier (personal conversation with young Roma girl, March 2012). Today, this young girl is completing her doctoral studies and will be the first Roma woman in Slovenia to have obtained a doctorate. It is common knowledge that children from a poor environment are more willing to accept the justifications of experts who direct them to special schools. However, some research has proven the opposite, i.e., children who were materially and socially supported became more successful with better learning outcomes despite belonging to an ethnic minority (Krek, 2005; Macura-Milovanović, 2006; Peček and Lesar, 2006; Rorke and Wilkens, 2006). This constitutes important knowledge for social workers because it shows that positive encouragements and enabling positive experiences of underprivileged children can bring better results, and improve the development of their sense of being included and appreciated.

Roma Women

Roma women often experience double discrimination: first as women in their own community (sexual discrimination), and, second, as members of the Roma minority in the wider community (ethnic discrimination). Both forms of discrimination frequently coexist. Social workers often believe that violence, aggression, and conflict behavior are part of Roma culture, and part of their 'Romani nature' (Urh, 2009). This behavior among Roma people is considered more acceptable by mainstream society. It is also why experts often do not intervene or intervene much later than they would in the case of violence or child neglect in a non-Roma family, or in marriages between minors among the Roma. In the latter instance, social workers who addressed one such case attributed the problem to Roma culture rather than defining it as sexual abuse. This exemplifies the denial of sexual abuse. When a Roma woman becomes a victim of violence and looks for expert support, she is mainly seen as a Roma, or a member of the Roma community, rather than a victim of violence. Therefore, ethnicity becomes closely interrelated with pathologization as a "process where a certain individual's

or group's ethnic/cultural characteristic[s] [are] constructed as natural and innate, and described with medical and psychological concepts determining individuals or groups as being prone to certain physical and mental illnesses, pathological violence and lower intelligence or even mental underdevelopment" (Zaviršek, 2010: p. 91). Expert workers who do not reflect on their prejudices, and do not acquire knowledge about ethnically sensitive work principles (Devore and Schlesinger, 1999), allow their assumed stereotypes unintentionally and sometimes unconsciously to influence their professional work (Urh, 2008, 2011). This means that their practice maintains existing forms of discrimination or creates new ones.

In many Romani traditions, Roma women are expected to assume the role of a woman at a very early age, to get married young, and have children early. All these roles prevent Roma women from accessing the labor market and make it difficult for them or even impede their having a family and working life at the same time. Particularly vulnerable are underage Roma girls who take on the caring role (for younger brothers and sisters or their own children), thereby interrupting their schooling before they have completed it. This is why a low education rate and a high illiteracy rate are characteristic of Roma communities throughout Europe (Barany, 2002; Corsi et al., 2008; Minority protection, 2001, 2002). The European report on the position of Roma women (Corsi et al., 2008: pp. 107–108) reveals a high rate of poor education among the Roma living in the countries included in the report.

The low education rate is one reason for the low employment rate of Roma people, but it is not the only one. Cases of prejudice and discrimination against Roma workers at the workplace by their employers and coworkers are evidenced across Europe. Apart from these, Roma women encounter additional obstacles, namely, having to take on their traditional role in the family, experiencing frequent pregnancies, and lacking qualifications and knowledge, which results in their having an even higher unemployment rate than Roma men (Corsi et al., 2008: p. 119).

One of the most debated areas regarding the rights of Roma women concerns their reproductive rights. Special rooms are known to exist for Roma women in maternity hospitals, e.g., 'Gypsy rooms' in Hungary (Izsák, 2004), along with worse health care treatment in general (OSI, 2001, 2002). The rooms for Roma women also reflect their stigmatization and their ascribed uncleanliness. The most frequent cause of their being separated lies in the implicit fear of non-Roma that coming in contact with Roma people leads to becoming infected by the stigma that they are supposedly transmitting. In a way, the rooms for Roma women represent a social distance creating and maintaining differences between 'clean' and 'unclean,' and maintaining the discourse of purity (Douglas, 2005) and stigmatization (Goffman, 1991).

Social Workers' Engagement with Roma Service Users

Racism in Social Work

Many reports recognize the vulnerability and experiences of exclusion and poverty of Roma children and Roma women are much higher and much more common than that among Roma community in general (see Web page of ERRC; also OSI 2001 and 2002 country reports). This recognition constitutes important knowledge for social work, which should trigger responses from social services. Social work seems to be the 'ideal' profession to contribute to the abolition of discrimination because of its insights into microlevel dynamics, knowing peoples' environments, social networks, and their everyday experiences; and having actionable knowledge about methods of working with marginalized social groups, professional ethics, and an understanding of sociological phenomena. Nonetheless, relations between social workers, who belong to the majority population, and Roma people, who face discrimination, are often not satisfactory (on either side) and inefficient. This can be seen in legalistic approaches or traditional social work relationships where the social worker is an expert and Roma service users are passive recipients of the services, and many unintentional, implicit racist responses. They are often treated through racist practices reflected in stricter control over their use of social benefits, the limitation or abolition of social benefits due to nonfulfillment of certain conditions only applying to Roma people, indifference, the passive attitudes of social workers who conduct 'ping-ponging' strategies by sending Roma service users from door to door, and placing responsibility for improvement on the Roma themselves (victim blaming) or other institutions. Every real-life case shows that expert services and public discourses refer to the cultural relativism and pathologization of Romani culture, especially in relation to deviant behavior such as violence against women and children, alcoholism, child neglect, and sexual abuse. In this way, social work contributes to racist practices or maintains the status quo.

Antiracist Responses

Social services are not immune from racist influences in their personal, cultural, and institutional contexts, making the integration of antiracist principles (Dalrymple and Burke, 2003; Dominelli, 1988; Thompson, 2001) into social work practice important. In Great Britain, social work has a rich history of antiracist social work development in the educational system as well as in practice from the 1980s onward and has influenced the rise of these perspectives in the social work education in other Western European countries. However, in Eastern Europe, antiracism is in its infancy. Until recently, ethnically sensitive and antiracist theory had attracted little attention in Eastern Europe compared to other social work topics (Urh, 2008; Zaviršek, 2007). One influential reason was political. The official ideology of the communist/socialist leadership in the previous political system until the end of 1989 focused on class equality, which was to overcome all other differences including gender, ethnicity, age, and religion. The fact that social inequalities were an undesirable and politically conflicting subject of discourse hindered the development of antiracist social work.

There is a strong need to develop a culturally sensitive learning model for social workers (Devore and Schlesinger, 1999; Laird, 2008; Thompson, 2001) that is based on ethnic/cultural sensitivity and antiracist principles. The model is based on the idea of recognizing the cultural needs and differences of local ethnic groups, as well as antiracist principles that recognize discrimination and oppression (Dominelli, 1988). One crucial component is an understanding of historical

experiences of the discriminated groups. This would enable social workers to raise their awareness about the discriminated groups and their collective experiences of not being accepted as belonging in the societies that they live within. It also offers a better understanding of certain types of their behavior (fatalism, conformism, passivity, and distrust), which is often the result of the prolonged experience of exclusion and being underprivileged (Urh, 2009). Understanding the dynamics of racism, which have been changing historically and taking on different forms (Dominelli, 2007), also enables social workers to understand its complexity – its extensiveness, multidimensionality, and how the many levels of racism are intertwined and influence each other (Dominelli, 1988; Jones, 2002; Thompson, 2001).

How should social workers respond to the ethnic reality of Roma people or Travellers whose origins may be different but have marginalization in common? In the United Kingdom, special emphasis is placed to education of Traveller children's families (Cudworth, 2008). Local education authorities ensure the availability of education for all school-age children in the area, whether permanently or temporarily that is appropriate to their age, ability, and aptitude. This is of particular relevance to Traveller children.

One of the recognized examples of good practice can be seen in community social work from Haringey Council (UK). Social workers follow the community social work model to provide access to education for Travellers, Gypsies, and Roma families, thereby raising the achievements of Traveller, Gypsy, and Roma children and young people, promoting Traveller and Gypsy culture in schools, and helping Traveller, Gypsy, and Roma pupils and young people to achieve their full potential (Davis, 2010). The community social work model is also recognized as one the most successful models working with marginalized Gypsy communities in Eastern Europe (Schuringa, 2005; Rorke and Wilkens, 2006). The main focus of the community model is shifting from 'the culture of poverty' toward 'the culture of development' (Schuringa, 2005: p. 20). The community development approach refers to the establishment of mechanisms for mobilizing community resources, which lead to community problem solving through a grassroots approach. The Roma are seen as subjects and participating fully in all stages of the work and are not treated as passive objects of support provided by the others (top-down approach). Its main characteristics are building on a community's strengths, partnership, and emancipatory approaches, which also allow for positive experiences (e.g., feeling their own capabilities and engendering responsibility).

Many principles of good practice are derived from the Open Society Institute's (OSI) many years of working with Roma people. Developing different integrative projects for Roma people over the years, OSI has learned not to fund projects that in their design, budgeting, and implementation neglect the key issues of structured or substantive Romani involvement and partnership; are devoid of strategic value; have no prospect of sustainability; leave no worthwhile legacy or concrete lasting results; projects that fail to make connections between inputs and outcomes or confuse means and ends; offer no clear outcome that justifies activities, training sessions, and seminars; and neglect to include Roma in the processes of monitoring and evaluation (Rorke and Wilkens, 2006).

Cultural advocacy is one of the competences of culturally competent social workers. Being an advocate for Gypsies/Travellers means to defend, support, and argue for them on individual and/or collective levels with the intention of improving their quality of life and ensuring their citizenship and civil rights. The goal of the cultural advocacy is to strengthen marginalized ethnic communities and encourage their emancipation. Cultural advocates understand and respect cultural differences and experiences of certain communities, and serve as mediators between cultures. In a way, cultural advocacy in social work is the voice of marginalized and often unheard members of ethnic minorities.

Recommendations for Future Practice and Research

Despite the rise of antiracist and ethnically sensitive social work education in the United Kingdom, Canada, and the United States from 1980 onward, East European countries still remain mostly without adequate literature regarding this field. In these environments, there is a strong need to develop culturally sensitive learning models for social workers that are based on ethnic/cultural sensitivity and antiracist principles.

In the last decade, there have been several publications about Roma peoples, in which the authors focus mainly on theoretical perspective and discuss their situations. These are valuable contributions to understanding their ethnic reality and have triggered several discussions about discrimination of Roma people. A disadvantage of these publications is that they rest at the level of analyzing the current situation and problematizing existing systems without focusing on the question of how to tackle Roma peoples' exclusion.

Another problem with many publications is the absence of Roma peoples' voices, thus disadvantaging them. Also, social workers are usually members of ethnic majorities. Therefore, one future role of the profession is to recruit ethnic minority social workers. This is not an easy task since many members of ethnic minorities are subjected to discrimination also through the field of education – which offers social work another challenge, namely, to create circumstances that would enable inclusion. This cannot be done overnight, but needs long-term social action:

- Provide Roma employment opportunities that will reduce their dependence on social benefits and provide positive role models for young generations.
- Provide support to include Roma people in sociopolitical discourses that empower the whole community.
- Be critical of negative media representations of Roma people that generate conflictual attitudes to the whole community, proposing instead positive ones.

From the perspective of research, understanding the position of researchers is important in avoiding their contributing to the creation of 'otherness' (Fine, 1994; Dominelli, 2007). This makes adopting an emancipatory research approach (Humphries, 2000) and following 'the natives' point of view' crucial (Geertz, 1974). Respecting and following this perspective makes 'the objects' of the research into 'subjects,' gives them voice, and encourages them to write their own biographies. Emancipatory research enables the researchers to

avoid one-dimensional 'expert' positions, the manipulation of ethnic minority peoples' realities, and misinterpretations of their feelings.

Social work should more strongly and explicitly accept the role of promoting social change and acting as a catalyst between institutions and the community over being an actor promoting bureaucratic demands (Urh, 2009). Social workers have to constantly rethink their position of being supportive on one side and controlling on the other. Neil Thompson (2001: p. 11) challenges social workers to think about whether they are a part of the solution or a part of the problem because "… a social work practice which does not take into account oppression and discrimination cannot be seen as a good practice …" (Thompson, 2001: p. 11).

Rorty, Richard (1931–2007)

Maria Baghramian and Fergal McHugh, School of Philosophy, University College, Dublin, Ireland

Published by Elsevier Ltd.

Abstract

Richard Rorty (4 October 1931–8 June 2007) is a highly influential American philosopher who is as divisive as he is popular. Rorty's many writings touch on major themes within both analytic and continental philosophy. Issues in epistemology, philosophy of mind, philosophy of science, and naturalism featured centrally in his early work. His later writings placed increasing stress on questions of democracy and culture. However, Rorty's 'great theme' is philosophy itself, and his relentless interrogation of philosophy's place and purpose both inside and outside the academy is unmatched in contemporary philosophy. The present article provides an overview of central features of his thought under the headings of 'Anti-representationalism,' 'Pragmatism,' and 'The Scope and Role of Philosophy.' The examination is loosely chronological; however, since Rorty's thought demonstrates deep continuities, each heading presents an aspect of his thought rather than, exclusively, a period of his development.

Life

Richard Rorty was born in New York in 1931 to James Rorty and Winifried Rauschenbusch. Rorty was raised in New York City and Flatbrookville, New Jersey in a predominantly left wing but anti-Stalinist political environment. He entered the University of Chicago in 1946, starting at the age of 15 years where he studied with greatest of the logical positivists Rudolf Carnap and also Leo Straus. After completing his MA in 1952, he moved to Yale where he received a PhD in philosophy in 1956 with a dissertation on the *Concept of Potentiality* under the supervision of the metaphysician Paul Weiss. After a brief stint in the army signal corps, he taught at Wellesley College (1958–60) and Princeton University (1961–82). At Princeton, Rorty was immersed in the problems, texts, and method of analytic philosophy, which dominated the philosophical culture there. The fruit of that immersion was the groundbreaking *Philosophy and the Mirror of Nature* (1979), a work that was strongly critical of that tradition while attempting to supply impetus for its renewal. Rorty's next move, in 1982, was to the University of Virginia where his primary teaching role shifted from 'Professor of Philosophy' to 'Professor of Humanities.' The move to the University of Virginia both enabled and complemented his increasing interest in 'continental' philosophers such as Derrida, Foucault, and Habermas. *Contingency, Irony and Solidarity* (1989), a somewhat polemical work ranging across topics from epistemology to modernist literature, is an important product of Rorty's broadened horizons. Rorty remained at the University of Virginia until 1998 when he took up a chair in the Department of 'Comparative Literature' at Stanford University where he saw out his teaching career. He retired in 2005. Rorty's fourth volume of philosophical papers, *Philosophy as Cultural Politics* was published in 2007. He died in June of the same year from pancreatic cancer. In a short essay published posthumously in *Poetry* (November 2007), Rorty wrote of his regret at not having spent more of his life with poetry:

> Cultures with richer vocabularies are more fully human – farther removed from the beasts – than those with poorer ones, individual men and women are more fully human when their memories are amply stocked with verse.
>
> Rorty, 2010a: p. 521

This is a signature Rorty remark, wide-ranging, polemical, and yet precise, both heartfelt and ironic.

Work

The breadth of Rorty's writing is remarkable. The content of his numerous books and essays spans themes in epistemology and metaphysics, through a variety of literary forms, to ethics and politics. Rorty represents something of a puzzle for contemporary philosophy; he is an analytic philosopher by training as well as style of writing whose crucial interventions with respect to that tradition take the form of an attempt to close it down. His writings on pragmatism are central to a resurgence of interest in the classical pragmatists (William James and John Dewey) and the establishment of what has become known as neopragmatism; however, his interpretations are hotly disputed and criticized as selective and self-serving (e.g., Susan Haack, 1993: pp. 182–202). Rorty's interest in philosophy itself has resulted in him being called a 'philosopher's philosopher,' a surprising title given his popularity outside of philosophy, and indeed outside the academy (Hall, 1994: p. 3; Kraugerud and Ramberg, 2010: p. 49); he has also been called an 'anti-philosopher's philosopher' (Ramberg, 2009). It is tempting to regard Rorty as something of a contradiction; however, to do so, neglects the remarkable consistency and continuity of his thought. Rorty's writing, from his landmark introduction to the collection *The Linguistic Turn* (1967) to late essays such as 'Philosophy as Transitional Genre' (2004) enacts a deep preoccupation with metaphilosophical questions concerning the methods, the value, and ultimately the fate of philosophy.

Despite this 'inward' turn, Rorty's metaphilosophy rarely tended toward abstraction; his overriding metaphilosophical concern was the relevance of philosophy to our lives. It is, in fact, not possible to separate Rorty's metaphilosophical views from his substantive positions. Thus, the following chronological survey of his key positions in philosophy is an account of both the substantive and the metaphilosophical points at stake.

Antirepresentationalism

In *Philosophy and the Mirror of Nature* (1979), Rorty opposes himself to a conception of philosophy that thought of the "discipline as one which discussed perennial, eternal problems – problems which arise as soon as one reflects" (Rorty, 1980: p. 3). By contrast, *Mirror* is tasked with recounting the historical and social narratives both of how such problems were specified and why they have come to demand philosophy's attention. Certain 'ways of talking,' he argues, have become remote from the purposes for which they were developed, they have become obsolete, in certain circumstances perniciously so. Most notably, a specific 'picture' has come to dominate the way philosophers think about our relation to reality, a picture that is neither obligatory nor useful.

> The picture which holds traditional philosophy captive is that of the mind as a great mirror, containing various representations – some accurate, some not – and capable of being studied by pure, non-empirical methods.
>
> Rorty, 1980: p. 12

This is how Rorty begins a career-long attack on what he characterized as the prevailing 'representational paradigm' both illustrated and in part produced by the 'ocular metaphor' of 'mirroring.' The figure of the mirror articulates an understanding of knowledge as a relationship between a mind and the world in terms of representation. Philosophy builds on this understanding, claiming as its own a specialized domain of knowledge about representation, specifically about what counts as truly representing the world. Rorty's response is to contextualize the view, to show that the view has a history and to reject the idea that it is compulsory or natural. In a language influenced by Michel Foucault, Rorty seeks to show "epistemology-centered philosophy as an episode in the history of European culture" (Rorty, 1980: p. 390). In the account Rorty provides, 'representationalism,' a paradigm routed primarily in the Cartesian epistemic turn in philosophy, achieves its institutional apotheosis in the work of Kant. Kant combined the best insights of rationalist 'mirror talk' (encapsulated by Cartesian clear and distinct ideas) and empiricist 'mirror talk' (Lockean and Humean conceptions of ideas and impressions) into 'representations' that are actively synthesized through specialized conceptual capacities only describable at a 'transcendental level.' In Rorty's account, Kant's putatively stable blend of empirical realism and transcendental idealism carved out a specific domain of reflective activity that supported the requirements of the empirical sciences while simultaneously positing a transcendental domain immune to the methods of those sciences and requiring specialized investigation with specialized tools. The mind (or in Rorty's parlance the 'Mind') is a key invention of Kant's revolution in philosophical approach, securing a place for the study of 'mirroring' at a level inaccessible to empirical means. At the outset of his career, Rorty had advocated the disappearance theory of the mind (Rorty, 1965), a precursor of the influential 'eliminative materialism,' where mind talk was to be eliminated from a naturalist description of the world to be replaced by a scientific vocabulary. This approach was subsequently softened somewhat; however, the 'capital M' mind remained a key site of attack. Crucially, for Rorty the relationship between mind and world is not one of representing but 'coping': "[a]s long as we think of knowledge as representing reality rather than coping with it, mind or language will continue to seem numinous" (Rorty, 1982: p. 202). More recently, he countered the traditional privileging of mind with the deprivileged social account: "the mind is not a representational apparatus, but rather a set of norm-governed social practices" (Rorty, 2007: p. 158).

Rorty's criticisms are not merely leveled at the Kantian and post-Kantian traditions but also at contemporary analytic philosophy, particularly the 'linguistic turn,' which he sees as an "attempt to find 'successor subjects' to epistemology" (Rorty, 1980: p. 10). While for many, a gulf separates Kant's 'idealism' from Russell and Frege's 'descriptivism,' from Rorty's perspective all these views are underwritten by unquestioned allegiance to the representational paradigm.

> Without the notion of the mind as mirror, the notion of knowledge as accuracy of representation would not have suggested itself. Without this latter notion, the strategy common to Descartes and Kant – getting more accurate representations by inspecting, repairing, and polishing the mirror, so to speak – would not have made sense. Without this strategy in mind, recent claims that philosophy could consist of "conceptual analysis" or "explications of meanings" or examination of "the logic of our language" or of "the structure of the constituting activity of consciousness would not have made sense."
>
> Rorty, 1980: p. 12

Rorty divides the history of philosophy into two distinct camps of systematic versus edifying philosophers. The divide cuts across the more conventional division between analytic and continental philosophy. Hegel and Husserl are system builders as are a great majority of the empiricists, rationalist, and analytic philosophers. While, the later Wittgenstein, Heidegger, and Dewey are concerned with 'edification,' with creating a space within philosophy that enables us to grow and develop in direct opposition to the approach where philosophy seeks to provide "'grounding' for the intuitions and customs of the present" (Rorty, 1980: p. 12). Wittgenstein's therapeutic mode shows how philosophical problems force themselves on us through captivating pictures, but his approach 'needs to be supplemented by historical awareness'; Heidegger's historical approach enables us to "distance' ourselves from the tradition' to tell a historical story about how the 'captivating' picture emerges. However, neither Wittgenstein nor Heidegger pays enough attention to the 'social perspective' of the picture's emergence (Rorty, 1980: p. 12). Dewey provides that crucial 'social perspective' but also, as part of that perspective the idea of an aesthetic mode of being that fills out the idea of 'coping.' In Rorty's words, Dewey seeks a "culture no longer dominated by the idea of objective cognition but by that of aesthetic enhancement" (Rorty, 1980: p. 13). All three contribute to Rorty's call for a change in our overall understanding of philosophy.

The cultural-political themes and motivations that dominate Rorty's later writings are already a feature of *Mirror*. Rorty

claims: "If we see knowledge as a matter of conversation and of social practice, rather than as an attempt to mirror nature, we will not be likely to envisage a meta-practice which will be the critique of all possible forms of social practice" (Rorty, 1980: p. 171). The edifying philosophers help us to recast our relation with reality in terms of 'coping' rather than 'representations.' Coping is this practical activity that releases us from the constraining chimera of 'mirroring': "[w]e should not look for skyhooks, but only for toeholds" (Rorty, 1991b: pp. 13–14).

Pragmatism

Rorty, more than any other contemporary American philosopher, is responsible for the resurgence of what has become known as neopragmatism in contemporary American philosophy. Pragmatism, for Rorty, first and foremost, is a kind of antiessentialism with respect to philosophical categories such as truth, knowledge, and morality (Rorty, 1982: p. 162), and a counterforce to the foundationalist traditions of modern philosophy since Descartes. A second hallmark of pragmatism is its resistance to unhelpful dichotomies such as the

> epistemological difference between truth about what ought to be and truth abut what is, nor any metaphysical difference between facts and values, nor any methodological difference between morality and science.
> Rorty, 1982: p. 163

In this Rorty shares common grounds with his long-time philosophical interlocutor Hilary Putnam. A third feature of pragmatism is one that we now most closely associate with Rorty and is at the heart of Rorty's disagreement with not only many of the philosophers in the analytic tradition but also with Hilary Putnam:

> [Pragmatism is] the doctrine that there are no constraints on inquiry save conversational ones – no wholesale constraints derived from the nature of the objects, or of the mind, or of language, but only those retail constraints provided by the remarks of our fellow inquirers… The pragmatist tells us that it is useless to hope that objects will constrain us to believe the truth about them, if only they are approached with an unclouded mental eye, or a rigorous method, or a perspicuous language… The only sense in which we are constrained to truth is that, as Peirce suggested, we can make no sense of the notion that the view which can survive all objections might be false. But objections – conversational constraints – cannot be anticipated. There is no method for knowing when one has reached the truth, or when one is closer to it than before.
> Rorty, 1982: p. 165–166

In parallel to the picture of 'the mirror' pursued in *Philosophy and the Mirror of Nature*, Rorty's pragmatism attempts to release us from the grip of the picture of 'the world.' In a recent essay Rorty writes:

> Despite my veneration for Wilfrid Sellars, who originated this talk of manifest and scientific images, I would like to jettison these visual metaphors. We should not be held captive by the world-picture picture. We do not need a synoptic view of something called "the world." At most, we need a synoptic narrative of how we came to talk as we do. We should stop trying for a unified picture, and for a master vocabulary. We should confine ourselves to making sure that we are not burdened with obsolete ways of speaking, and then ensuring that those vocabularies that are still useful stay out of each other's way.
> Rorty, 2010b: p. 58

Pragmatism, as Rorty presents it, helps to free us from yet another pernicious dichotomy, that of a division between the world and the conceptual schemes that supposedly categorize it and render it intelligible. Following Donald Davidson (Davidson, 1974), Rorty finds the very division between a scheme and the world as something unfitted falling under it, not only incoherent but also pernicious both for those who accord them metaphysical status and for those who locate them in history (and any position in between).

> The notion of "the world" as used in a phrase like 'different conceptual schemes carve up the world differently' must be the notion of something completely unspecified and unspecifiable-the thing-in-itself, in fact. As soon as we start thinking of "the world" as atoms and the void, or sense data and awareness of them, or "stimuli" of a certain sort brought to bear upon organs of a certain sort, we have changed the name of the game. For we are now well within some particular theory about how the world is.
> Rorty, 1982: pp. 14–15

In his highly influential book *Contingency, Irony and Solidarity* (1989) and a number of papers to follow, Rorty is at pains to distinguish between the goal of giving meaning to our lives and thoughts with reference to a 'nonhuman reality' versus the alternative of envisaging their role in terms of contributions to a community. Realist philosophers, since Plato, have followed the first route and relaying on the correspondence theory of truth, a key component of the metaphor of the mind as a mirror, to achieve the ideal of objectivity with no reference to our historical situatedness. The alternative route is to seek solidarity with a community of enquirers, to reject the dualism of objective and subjective, knowledge versus mere opinion, and to eschew the talk of truth in other than in the sense of complimenting or commending the best beliefs and practices available to us at any given time (Rorty, 1985/1991) where the 'us' is a community of thoughtful, well-informed, and reasonable but historically located thinkers. The approach is best captured in the writings of the pragmatist philosophers' attempt to 'reduce objectivity to solidarity' (Rorty, 1991b: p. 21).

Rorty calls this approach 'ethnocentrism' and resists the charge, leveled at him by Hilary Putnam among many, that the abandonment of the ideal of mind-independent objectivity amounts to a form of relativism (Baghramian, 2004: pp. 144–151). He thinks relativism is no more than the claim that all beliefs are equally good and he finds the idea incoherent. Ethnocentrism, on the other hand, is the "purely negative point that we should drop the traditional distinction between knowledge and opinion, construed as the distinction between truth as correspondence to reality and truth as a commendatory term for well-justified beliefs" (Rorty, 1991b: pp. 23–24).

From the perspective of his pragmatism, dispensing with talk of 'truth,' 'knowledge,' and even 'the world' as

metaphysically inflated categories provides release from a series of endless and fruitless debates that are only pertinent if one's thinking is constrained by the metaphor of mirroring. Knowledge is belief justified within a social context, while truth is a compliment paid to the best-justified beliefs we have at any given moment, beliefs that 'we can defend against all comers.' We do not need to refer to a mind-independent world or objective accuracy of representations in our understanding of these and other cognate epistemic concepts. For Rorty, the very idea of 'the world' produces the illusion of a vantage from which distinctions between true by our lights and true simpliciter, but such world is 'well lost' (Rorty, 1982: p. 3), as we cannot make sense of the very idea of its existence outside of our linguistic and social practices. The pragmatist alternative allows us to construct a narrative of how we created and lost the world. The mode is ironic, since from the pragmatist vantage the world was always a story and the story is told for the purpose of edification. 'Solidarity,' however, is not a purely abstract philosophical notion, but plays a major role in Rorty's political outlook. As an unapologetic liberal, Rorty sees solidarity as the basis for obtaining incremental improvements in the scope of our freedoms and rights, and to help, by Rorty's lights, in the core liberal aims of preventing and reducing cruelty and decreasing intolerance. In politics, as in philosophy, the task is to be carried out through replacing confrontation by conversation within an ever-growing circle of peers. Philosophy, in its pragmatist form, is an aid to democratic politics, in so far as it encourages such conversation.

The approach results in one of the important intellectual advances of our century a 'steady decline in interest in this quarrel between Plato and Nietzsche about what we are really like' (Rorty, 1998: p. 169); there is now, Rorty thinks,

> a growing willingness to neglect the questions "What is our nature" and to substitute the question "What can we make of ourselves." We are much less inclined than our ancestors to take "theories of human nature" seriously, much less inclined to take ontology or history or ethology as a guide to life. We are much less inclined to pose the ontological question "What are we?" because we have come to see the main lesson of both history and anthropology is our extraordinarily malleability. We are coming to think of ourselves as the flexible, protean, self-shaping animal rather than as the rational animal or the cruel animal.
>
> Rorty, 1998: pp. 169–170

Here, too, Rorty remains the eliminativist philosopher *par excellence*. We not only should eliminate the reified mind talk and Truth talk from philosophy but also should stop thinking of ourselves in essentialist terms, as creatures endowed with a specific nature.

Rorty's version and interpretation of pragmatism has come under sustained attack. Susan Haack, for instance, an unflinching critic, thinks Rortyism is no more than vulgar pragmatism and accuses him in have misrepresented the work of classical pragmatists, James, Dewey, and Peirce (Haack, 1993: pp. 182–202). Defenders, on the other hand, have hailed him as crucial revivalist, a philosopher who has delivered previously unfashionable pragmatist thinking to new audiences, reinvigorating the pragmatist ideas in the process.

The Scope and Role of Philosophy

Much of Rorty's work, as indicated above, has a metaphilosophical tone. This was clear even in his very early publications, but it is not always an easy task to distill a unified account of philosophy from Rorty's writings on the topic. A few strands of thinking, however, are prominent. The *Linguistic Turn* (1992) signaled Rorty's nascent interest in a historic and contextualized understanding of philosophy. *Philosophy and the Mirror of Nature*, where Rorty puts the current "predicament of philosophy" (Rorty, 1980), as he sees it, in the historic context of a turn to epistemology, expresses this 'genealogical' understanding of philosophy even more completely.

> In this book I have offered a sort of prolegomenon to a history of epistemology-centred philosophy as an episode in the history of European culture… A proper historical treatment would require both learning and skills I do not possess. But I would hope the prolegomenon has been sufficient to let one see the contemporary issues in philosophy as events in a certain stage or a conversation – a conversation which once knew nothing of these issues and may know nothing of them again.
>
> Rorty, 1980: pp. 390–391

He also notes, "[a]lmost as soon as I began to study philosophy, I was impressed by the way in which philosophical problems appeared, disappeared, or changed shape as a result of new assumptions or vocabularies" (Rorty, 1980: p. xiii). The historical perspective makes us sensitive to a lack of fundamentals and the apparent mutability of philosophical problems themselves, themes that permeate Rorty's work.

A second prominent tendency is an invitation to modesty and even quietism in philosophy. Rorty had questioned the 'cash value' of philosophy even in his earliest writings. In an early essay 'The Philosopher as Expert' (1958–61/2009), unpublished in his lifetime but recently included in the 30th anniversary edition of *Mirror*, Rorty already demonstrates both the deep metaphilosophical tendencies that will inhabit his mature thought combined with a discomfort with the idea of philosophy as distinct set of jobs for which only the philosopher need apply. Thus, Rorty resists the assumption that "there is a body of special 'philosophical' truths, or the assumption that there is a special 'philosophical' technique that somehow works equally well on all problems, and is distinct from the ordinary, vulgar methods used to solve them" (Rorty, 2009: p. 421). In a new introduction written for the reissue of *The Linguistic Turn* (1992), Rorty remarked that in direct contrast to other types of inquiry such as science "what counts as philosophical knowledge seems itself to be a matter of opinion" (Rorty, 1992: p. 2). It is for Rorty an important irony that this lack of consensus has not prevented philosophers from believing that their discipline should critique and regulate what counts as knowledge within specific empirical domains. Philosophy, Rorty tells us, is not in a position to sort out its own affairs, never mind the affairs of other activities. There was, Rorty argues, a particular historical juncture at which Philosophy (with a capital P) served a 'useful purpose,' for example, "by suggesting ways of dealing with the triumph of mechanistic materialism" (Rorty, 2010b: p. 56) without recoil into some form of supernaturalism. That purpose is now achieved and the

attendant self-image of the discipline only possessed meaning within that task; that self-image should no longer be honored. Instead, Rorty encourages us to replace the vocabulary of discovery with that of creation; our task (or more precisely our tasks) *qua* philosophers is to create, to innovate, and to work for the better of the human conversation (and the humans who contribute to it) through inventiveness, playfulness, and brio. In *Contingency, Irony and Solidarity*, Rorty named this 'activity' irony. In its broader, institutional practiced form it is 'cultural politics'; 'Philosophy as Cultural Politics' is the title and theme of his last collection of papers.

Thirdly, Rorty's conception of traditional philosophy crucially exceeds institutional boundaries. Even in *Philosophy and the Mirror of Nature*, the term 'philosophy' is not restricted to analytic philosophy. "[T]he difference between 'analytic' and other sorts of philosophy is relatively unimportant – a matter of style and tradition rather than a difference of 'method' or of first principles" (Rorty, 1980: p. 8). However almost from the beginning, Rorty seems to express a preference for 'continental philosophy,' specifically those types of continental philosophy that combine social and cultural critique with a deep suspicion vis-à-vis the prior Western philosophical tradition. A feature of the kind of continental philosophy Rorty likes is its embrace (at least in his reading) of contingency as well as the edifying form of philosophizing. But his writing, as well as his academic career, also crosses the boundaries between philosophy and literature. He also wishes to transgress the 'purity of academic disciplines' by inviting philosophers to become participants in debates on moral and political topics that shape our lives and our times. As Rorty remarks in the introduction to his fourth volume of papers

> The more philosophy interacts with other human activities – not just natural science, but art, literature, religion and politics as well – the more relevant to cultural politics it becomes, and thus the more useful. The more it strives for autonomy, the less attention it deserves.
>
> Rorty, 2007: p. ix–x

Intellectuals, Rorty thinks, have a duty "to function as citizens of a democracy," "to use the mechanisms of democratic government to help prevent the rich from ripping off the poor, the strong from trampling on the weak" (Rorty, 1991a: p. 490), and philosophy should not turn its back on these tasks, and yet he points out that in "political deliberation, philosophy is a good servant but a bad master. If one knows what one wants and has some hope of getting it, philosophy can be useful in formulating redescriptions of social phenomena" (Rorty, 1999: p. 232).

Legacy

The impact of Rorty's work can be felt far beyond the boundaries of what is typically considered academic philosophy; however, any appreciation of this influence must begin with an assessment of his philosophical legacy. Rorty's legacy can be divided with respect to what commentators take to be his most significant work, *Philosophy and the Mirror of Nature* or *Contingency, Irony and Solidarity*. Those philosophers who take themselves to inherit from the Rorty of *Mirror*, broadly speaking analytic philosophers, are at once critical and admiring. In many instances, their aims are to rehabilitate a Rorty who in numerous ways and on a host of issues simply went too far; their task is to retain the best of his insights while calming or abandoning his rhetoric. For example, John McDowell shares Rorty's belief that the philosophical problems posed within the Cartesian and British empiricist traditions are to be addressed therapeutically rather than to be straightforwardly answered or solved, but he thinks Rorty goes too far in denying the idea of an answerability to the way things are that goes beyond our communal say so (McDowell, 2000: p. 110). Other contemporary analytic philosophers who inherit from Rorty include Robert Brandon, Michael Williams, and Huw Price. Those who read *Contingency, Irony and Solidarity* as Rorty's most important work, broadly speaking continental philosophers, tend to be more focused on the possibilities his work supplies for the pursuit of a postphilosophical mode of philosophy. They include Nancy Fraser who has further developed Rorty's concept of 'private irony' (Fraser, 1988, 1991) as part of her brand of feminist critical theory. Equally, Rorty's impact on the social sciences both extends from that work and is at its strongest where the social sciences and philosophy are at their most enmeshed; those social scientists who take Louis Althusser, Michel Foucault, Jacques Derrida, Jean Baudrillard, and Alain Badiou seriously are likely to be interested in what Rorty has to say concerning the active creation of vocabularies, the resistance to systematization, and the embrace of contingency in a mode of critical historicism. In an early essay 'Method, Social Science and Hope' (1981/1982), Rorty argued that the social sciences should not occupy themselves with scientific description at the expense of the normative, nor should they attempt to artificially separate these strands. Rather, they should concern themselves with being useful. Rorty recommends a "Deweyan approach to both social science and morality, one which emphasizes the utility of narratives and vocabularies rather than the objectivity of laws and theories" (Rorty, 1982: p. 195). The social scientist, thinks Rorty, should be in the business of telling good stories that make our lives better.

Appropriately, for a polemical philosopher such as Rorty his relation to key thinkers from the continental tradition is both complex and contested. For example, his reading of Derrida as a poet rather than a philosopher is, by some lights, typical of Rorty's shallow 'way' with philosophical texts (e.g., Bouveresse, 2000: pp. 133–134). Also, despite his leftward leaning, Rorty's ethnocentrism sits uncomfortably with those who aim to undo what they see as Enlightenment-inspired structures of domination masked behind a rhetoric of emancipation (e.g., Haber, 1994: pp. 43–72). For such critics Rorty is the effective steward of old-Europe enlightenment wolves in 'theory' laden sheep's clothing.

Finally, we might say that Rorty himself has, appropriately, attracted attention as an intellectual phenomenon that requires a sociohistorical account. In an innovative work *Richard Rorty: The Making of an American Philosopher* (2008), Neil Gross, a sociologist, has attempted to turn Rorty's ceaseless demand for context back on Rorty himself. In many ways, Gross's engagement with Rorty is exemplar of Rorty's influence on the social sciences and his lessons for the social sciences that there

is no such thing as a value-free, ahistorical mode of inquiry, that the question of context must always be addressed, and that the story of how we reached our 'present' must be told.

Abstract

Jean-Jacques Rousseau, 'citoyen de Genève,' lived a life of constant unrest. Having been part of the Parisian circles of Enlightenment for a short time, he became the successful outsider who wrote for a European public. In 1761–62, he published the three essential works that have continued to influence literature, philosophy, economy, sociology, and education into the twenty-first century. Rousseau delivered provocative ideas, which contradicted the mainstream. His thinking is paradoxical in a very attractive way. In education the basic concept of 'natural' and 'negative education' was considered to be the theory putting not religion or society but the child and its development in the center of respect. Rousseau influenced almost every reform movement in education, as well as eminent writers such as Jean Piaget and Maria Montessori. The progressive education of the twentieth century confirmed Rousseau's child centeredness and made it popular, although Rousseau, in his time, had no real impact on professional education and the development of schooling. His ideas were used by those interested in alternative education and society, and this was made possible by the strict dualism in Rousseau's thinking. Nature stands against society, and natural education was the opposite of artificial teaching, which used books instead of experience. Rousseau's language is at the same time elegant and sentimental, and together with his ideas explains his lasting influence.

Life and Work

Rousseau was born on 28 June 1712 and raised in Geneva, the center of Calvinism. Jean Calvin, not a native Genevan, published his magistral *Christinae Religionis Institutio*, the central work on education, in 1536. Its final version, dated 1559, justified general priesthood by way of the doctrine of predestination. Calvin dissolves the 'two empires' of laymen and ecclesiastical office in favor of a parish without differences, one which saw itself as an elected body (Calvin, 1957: III/21). Clergymen are chosen teachers whose sermon is intended to *educate* (Calvin, 1958: IV/1, 5) without the possibility of it being associated with primacy or hierarchy (Calvin, 1958: IV/74). Rousseau's life and work is, in many ways, a manner of dealing with Calvinism. The concept of *equality* determines the Social Contract, the theory of education and Rousseau's natural theology. Calvin's doctrine of grace is translated into the predestination of nature, along with a rigorous inwardness that has the only true form of education on its side. Virtue becomes a model for society given the education of man's nature. Calvinistic rigor fascinated Rousseau, following the banning and public burning of his books, he dispensed with the citizenship of the Republic of Geneva in 1763, but not, however, his membership in Calvin's church that he had renewed in 1754.

Rousseau's dramatic life (Cranston, 1991–97) (documents in *Le CD-Rom Jean-Jacques Rousseau*, 1999; Damrosch, 2005) is characterized by ascent outside the elite and by being an outsider. The young Rousseau completed an apprenticeship as an engraver, in view of education he was largely an autodidact. His wavering career run between Geneva and Paris, later included Switzerland and England, independently and restlessly all the time. Rousseau himself had attempted to gain control over his biography with the writing of his *Confessions* (Rousseau, 1961: pp. 1–656) that was published posthumously in 1782 and indeed determined the image of Rousseau since then. After various wanderings and low-level activities, Rousseau took up a position as a private tutor in Lyon in 1740 and wrote his first text on education (*Mémoire à Mr de Mably*: Rousseau, 1969: pp. 1–32). In 1742 Rousseau went to Paris, publishing his *Dissertation sur la musique moderne* in 1743. In 1749 Rousseau wrote the articles on music for Diderot's *Encyclopédie*, his first major literary success came one year later with the *Discours sur les sciences et les art*, which was awarded a prize by the Academy of Dijon. From 1756 on Rousseau, living now in the *hermitage* of Montmorency, concentrated on his three major works: the *Nouvelle Héloise* (1761), throughout Europe a successful, widely read novel; the *Contrat social* (1762), Rousseau's theory of society; and *Emile ou de l'éducation* (1762), the theory of 'new education.' Both books, the one about the social contract and that on education, were banned directly after publication and publicly burned in Paris and Geneva.

Since then Rousseau was on the run. He was granted asylum by the Prussian governor in Neuchâtel soon after his fleeing from Paris, at his place of refuge in Môtiers he was subjected to attacks by such differering authors as the general procurator of Geneva, Trochin, and his arch enemy Voltaire ('Sentiment des citoyens,' Voltaire, 1961: pp. 715–718). At the same time Rousseau became the idol of the generation of 'Sturm und Drang,' young *literati* from throughout Europe visited Rousseau in Môtiers and made him famous. In January 1766, after having passed more places on the run, Rousseau made for England following an invitation by David Hume. Both had wrong hopes and soon their relationship broke into pieces. Rousseau returned to France and worked, with increasing paranoia, on his autobiography which can be seen as an attempt at self-therapy. His precarious financial situation was revived at short notice in May 1778 when Rousseau and Therèse Levasseur, whom he had married in 1768 following a long-standing concubinage, moved to Ermenonville into an estate owned by Marquis de Girardin, Rousseaus's last benefactor. The sudden death on 2 July 1778 ended a very unlikely literary and

philosophical career, which was intended to be *à rebour* – contrary to convention.

Education and Society

The archbishop of Paris, Christophe de Beaumont, justified the banning and burning of Rousseau's *Emile* above all with the denial of the original sin. In fact Rousseau assumes that the nature of man is not tainted. "There is no original sin in the heart of man" (Rousseau, 1969: S. 322). In his state of defense against Beaumont, printed at the beginning of 1763, Rousseau formulated a far-reaching dualism, which since then has dominated political and educational conceptions. The two sides of dualism are *nature* and *society*; both are treated to be contradictious. The present social order contradicts human nature in every respect, society is the alienation of nature, and this explains the vices of men and the evils of life. The assumption of the original sin then is superfluous, man could live without sin if nature and society correspond and harmonize (Rousseau, 1969: pp. 966 et seq.). In this respect Rousseau had a post-Augustinian concept of education in mind which is developed in *Emile*.

Essentially, the theory has three axes: the political difference of *homme civil* and *homme naturel*, the assumption of phases of 'natural development,' and the anthropological difference of *amour de soi* and *amour propre*. Rousseau's concept of education is constructed using these axes. This concept is peculiar *not* because it stresses 'natural education,' a term that was established in educational discourses long before Rousseau (Mercier, 1961); the peculiarity arises, moreover, from the paradoxical attempt to solve the contradiction between nature and society *by way of education*. To this end Rousseau, already in the draft of *Emile*, the *Manuscrit Favre*, draws a distinction between two contrary types of education, that of *nature* and that of *society* (Rousseau, 1969: p. 58). They refer to two ways of life, the life of natural and of civil man both described contrary to Hobbes, who, in his *Leviathan* (1651), distinguished between *natural* and *social condition*. Society, for Hobbes, tames and cultivates nature, thus repression of nature is unavoidable. Rousseau reversed this argument, for him the social condition is that of ongoing civil war (bellum omnium contra omnes) while the natural condition is considered to be of presocial peaceableness. The education for the 'publique business' by Hobbes (1968: S. 289 et seq.) is completely ignored.

Rousseau justified his fundamental thesis in the second *Discours* dated 1765, which was subjected to the evolution of inequality (Rousseau, 1964: S. 109–194). Rousseau explains *inegalité* in the form of society's corruption of human nature, which originally was in a position to live harmoniously with man's own needs. What is called *homme sauvage* (savage man) is considered to exist on the basis of his own strengths, while the *homme civilisé* (civil man) develops social needs, which render him dependent and weaken his nature (Rousseau, 1964: pp. 135 et seq.). The division of labor, the development of knowledge, and the connected social differentiation (Rousseau, 1964: pp. 143 et seq.) forcefully brought about a progressive inequality among men. Leave is taken of the condition of innocence and natural freedom (Rousseau, 1964: p. 152), the invention of the *first* society irresistibly causes all those following (Rousseau, 1964: p. 178), for the prize of alienation of mankind from its own nature. In this respect *society* is the fall of men, not nature.

The theory of education in *Emile* picks up the evolution thesis and processes it with regard to the development of the child. This forces a reversal: the social condition does not follow the natural condition; moreover, the social condition is led back to the natural condition given that education can develop nature on the basis of its own potentials. Rousseau's risky experiment of thought goes as follows: If children are seen as the *homme sauvage*, education would have to apply to this condition entirely, provided that the social condition can be excluded for the duration of education. This assumption leads to *Emile's* basic scenario: an 'élêve imaginaire,' described in greater detail merely as an 'orphan,' is exclusively educated by a 'governor' outside any society. The scene is an anonymous countryside far away from corrupt cities and raw villages, i.e., independent from the social condition as Rousseau viewed it (Rousseau, 1969: S. 264, 267, 279). The place in which the story is told is described simply as 'au milieu des champs' (in the middle of fields) (Rousseau, 1969: p. 277) without any details regarding origin and personal history of the two protagonists. Insofar, the tale is not a novel of education but a *treatise* that is intended to describe the paradigm of true education. The *name* 'Emile' is presumably reminiscent of Plutarch (Shanks, 1927), it has no biographical meaning. Accordingly the governor is not given a name and is thus not distinguishable. Both are paradigms, not persons.

'Natural' is *negative* education. Rousseau largely draws on the phases of human development from the *Histoire Naturelle* by Buffon (1989: pp. 1–114). Again not the schema of 'development,' formulated at the beginning of the *Manuscrit Favre* (Rousseau, 1969: p. 60), is original but the linkage with the axes of educational theory. Rousseau understands the entire childhood as the 'age of nature,' which must take place outside the social condition. Thus the entire first education is *negative*. It consists not at all in teaching virtue or truth, but in avoiding vices and errors to grant the innocence of heart and the integrity of mind (Rousseau, 1969: p. 323). The concept of negative education is aimed against Locke (Rousseau, 1969: pp. 317 et seq.) whose *Thoughts Concerning Education* had been available in French in a translation by Pierre Coste since 1695 and had considerable influence. Locke's (1989: p. 142) central idea, "Children are to be treated as rational creatures," aroused a passionate contradiction in Rousseau. For him "*Reasoning* with children" (Locke, 1989: p. 142) was nothing other than the reversal of nature's plan. Reason (raison) is the aim of education, but the end cannot determine the beginning. "If children could understand reason there would be no need to educate them" (Rousseau, 1969: p. 317). Childhood must have its *own* manner (manière) of seeing, thinking, and feeling, which is not that of the adults (Rousseau, 1969: p. 319). Locke's concept of reason is that of adults outside the world of children.

It is above all this idea, the own world of childhood, that had justified Rousseau's fame in education, along with the paradisical metaphor of pure education outside society and the spontaneity of children that are considered to be led by immediate interests (intérests présents) (Rousseau, 1969: p. 358). Rousseau seems to be the creator of modern education,

which stresses the 'new' image of child and childhood. In this respect it is often overlooked that *Emile* clearly has a theological center, that the treatise ends by giving preference to republic, not to nature, and that the whole theory presents *two* concepts of education with differing gender forms. The center of *Emile* is the concept of 'natural religion,' justified in the *Profession de foi du Vicaire Savoyard*, a treatise within the treatise (Rousseau, 1969: pp. 565–635). Rousseau takes the role of the vicar who against the materialism of the Parisian philosophy announces a supreme being or an active creator who is assumed to be "King of Earth" (Rousseau, 1969: p. 382). Being in unison with creation cannot mean anything sinister: "Where everything is good nothing can be injust" (Rousseau, 1969: p. 588). The good can be seen in creation, justice eminates from the good, only a just person can live happily (Rousseau, 1969: p. 589), but the enthusiasm for virtue (Rousseau, 1969: p. 596) is an *inner* principle (Rousseau, 1969: p. 598), that of the heart and not of reason (Rousseau, 1969: p. 627). Consequently, the key to the profession of faith is the following: "We can be men without being scholars" (Rousseau, 1969: p. 601).

What Rousseau called "natural religion" (Rousseau, 1969: p. 607) is a *theology of the heart* (Osterwalder, 1995; cf Chevallier, 1994), it does not require any positive dogma, moreover inner enlightenment, that needs no teachers (pasteurs) (Rousseau, 1969: p. 609) but the inspiration of belief in seeing God's creation. Above all, Rousseau radicalizes the Calvinistic doctrine here, the metaphor of 'heart' signals independence even from the community of belief. 'Equality' is therefore not a social construction, which would require comparison with others but a sovereignty in solitude. 'Sovereignty' or *inner strength* presupposes identity *and* distance. Rousseau justified this difference with the relation between two instances of the soul called *amour de soi* and *amour propre*. The fact that *two* instances are mentioned violates again a convention of literature. In French virtue literature like La Rochefoucauld's *Maximes* (1665) or Blaise Pascal's *Pensées* (1670) 'amour propre' is the formula for egoism and self-love that has to be restricted by education. Rousseau used the formula in a new relation: He took over the negative meaning of *amour propre* but added a second positive instance, that of *amour de soi*. The positive instance grants that man looks only for himself and is content with the satisfaction of his own true needs. The negative instance, *amour propre*, leads to comparison with others and is never satisfied because nobody will give preference to others more than to himself (Rousseau, 1969: p. 493).

Loving and tender passions occur in *amour de soi*, hate and temper occur in *amour propre*, i.e., from comparison with others. Thus, man is all the more happier with the fewer needs he has and the more he can avoid comparisons with others; in contrast, the things which make man suffer ills and evils (méchants) are *too many* needs and *too ma*ny opinions, i.e., the dependency on others. Consequently, Rousseau develops the concept of 'éducation solitaire' (Rousseau, 1969: p. 341), which isolates the fictious Emile throughout his childhood, totally controls learning (la liberté bien réglée: Rousseau, 1969: p. 321) and stipulates the didactic scenario on the theory of natural requirements and needs. Therefore Emile does not receive lessons, is not provided with any written works and is excluded from all forms of cultural education. Only the *age de raison* – youth – requires formal lessons, the entire childhood should apply exclusively to nature which, of course, is only experienced in a *didactic* manner, i.e., extremely artificial. The governor (and he alone) arranges the entire experience, and it is not by chance that the island of Robinson Crusoe is the only literary evidence that Emile is given to read (Rousseau, 1969: pp. 455 et seq.).

The concept of *éducation solitaire* refers to the education of man (*faire un homme*: Rousseau, 1969: p. 248). However, in the beginning of the fifth book Rousseau introduces 'Sophie ou la femme,' i.e., he is forced to react to the difference in sex. The education of 'the woman' is given an equally generalized treatment as was previously the case with 'the child.' But now it is recognised as a *male* child and not as a sexless 'person' in general. Rousseau's *homme sauvage* is stated as male, namely 'strong,' 'sovereign,' and 'independent.' Sophie, the generalized women, is educated in a manner that she can see herself as being in complementary dependence to males. The education of sexes is therefore not equal, it is dissimilar (Rousseau, 1969: pp. 700 et seq.). This is subject to the precondition of sexual difference that cannot be dissolved or harmonized (Rousseau, 1969: p. 697). Because men want to seduce, they are dependent in the crucial moment; women have to agree and thus can say 'yes' or 'no.' This female strength can only be compensated by binding the woman to the house and forcing her publicly to virtuousness. The 'mutual dependency' is therefore not symmetric: men are dependent on women because of their desires (désirs), women are dependent on men as a result of their wishes *and* needs (besoins). Accordingly, "by the law of nature itself women are at the mercy of men" (Rousseau, 1969: p. 702), not vice versa.

Rousseau's treatise about true education ends with a grand tour (Rousseau, 1969: pp. 826–855), which is intended to introduce Emile to basics of government theory (Rousseau, 1969: p. 833), i.e., the doctrines of Rousseus's own *Contrat social*. Endeavors are made regarding "le dernière perfection" (Rousseau, 1969: p. 799), it is envisaged that the well-educated *man* now is to become a respectable *citizen*. The citizen's know-how is taught with the theory of the "social contract" (Rousseau, 1969: pp. 839 et seq.). Emile has to learn what defines the status of citizens (citoyens) and thus the constitution of society (Rousseau, 1969: p. 840). The small *republic* is given preference, one which can create an ideal relationship between population and government (Rousseau, 1969: p. 840). Obviously the Republic of Geneva, idealized by Rousseau during his lifetime, is the paragon for this thesis. The ideal Republic is seldom and thus hard to find. So the governor concludes his teachings on government as follows: The obligations of the citizen presuppose a true country (patrie), a country is true insofar it can be considered as a model of political virtue. Those who do not find their 'patries' will not face political abysm, "car qui n'a pas une patrie a du moins un pays" (Rousseau, 1969: p. 858).

The connection of education to society fails. Rousseau had two views on society, first the ideal of the 'contrat social' prevailing a model for social order that is mainly granted by the concept of *volonté génerale*, the general will behind all singular wills (Rousseau, 1964: pp. 361 et seq.), second the polemical description of general decadence within the existing society. In no place does society comply with the ideal, therefore the grand tour ends without result. The couple Emile and Sophie,

educated differently, are not released into society *as citizens* but led to marriage and family (Rousseau, 1969: p. 867). More is not possible, the ideal society inspired by the volonté générale and thus safe from the corruption of power is not realized anywhere. The social ideal has no social place. The decadent society, on the other hand, is morally not acceptable, the real society has its place but not a legitimate form. Thus, loneliness (solitude) is in the end stronger than sociality (Starobinski, 1971), because education will not change society but can only develop man's nature. The great project of 'humanization' through natural education (as stated by Ravier, 1941) fails due to its own ambitions and contradictions. 'Nature' in the framework of Rousseau's *Emile* is an artificial experience, learning is bound by didactic parameters, control is total, sentiment for the children's *own* world arises from the fiction of a good and equal nature that does not mirror any child's individuality (Oelkers, 2008).

Reception and Enduring Influence

The adoption of Rousseau's work demonstrates the often dramatic and always radical conflict between convinced supporters and equally convinced adversaries. Rousseau divides his readers until today, not the least because he wrote against reality. His ideals of antiquity, especially those of Sparta and Athens, suggest an *âge d'or* (Terrasse, 1970; Leduc-Fayette, 1974), which can be understood as an anticipation of the future, the renovation of the 'true society' that has been lost in history. Rousseau is therefore not by chance the hero of the Jacobins, his cult was established in the French Revolution (Barny, 1986) against all conservative theories who negate revolution in favor of long-term development of society without the sentiment of decadence. Rousseau's Social Contract represents the *new* society that conservatives can only deny. The tension between freedom and equality attributed to, and paradoxically and provocatively described by Rousseau, characterizes one major part of political theory up to John Rawls' reformulation of the *Contrat Social*. The same applies in similar fashion to the theory of 'natural education': Rousseau's *Emile* is a key source for Tolstoy and the reform movements of the nineteenth century, a central inspiration for Piaget (Oelkers, 1996) and the development of child psychology, and a milestone for *progressive education*.

Of central importance are the dualisms and thus Rousseau's language. He stresses contradictions and paradoxes between nature and society, men and citizens, children and adults, and not at least male and female. Even John Dewey, who refused dualisms, had to claim that Rousseau – and only he – was the founder of the theory of 'natural development' (Dewey, 1985: pp. 211 et seq.) as opposed to artificial schooling and thus read in a dualistic manner. Educational concepts are irritated by Rousseau, who is regarded as a 'classical writer' of education (Oksenberg Rorty, 1998), *because* of the unsolved paradoxes. The concept of education makes no attempt of solving the paradoxes and dilemmas, but left them open thus puzzling readers with keen contradictions, which are right and wrong at the same time. What counts is not logic but the heart, and this seems to be part of the success. Radical conclusions seem to be obvious, politics within a new society and to make this possible the education of 'new man' according to his own true nature. The famous ascription 'return to nature,' being part of nineteenth century's readings of Rousseau and nowhere stated by him directly, was regarded as a emancipation from alienation, thus a project of the left. But Rousseau was at the same time radical *and* conservative, society should return to the golden age, education should leave schooling for true nature, man should be first man and then citizen, it is this rigor without reality that fascinated Rousseau's readers, followers as well as opponents.

The theory of education is provocatively puzzling: The 'negative education' has no objective, nature develops itself. However, the learning process is subject to extreme regulations (Oksenberg Rorty, 1998: p. 248). The present should not be made a victim of the future (Rousseau, 1969: p. 309), but every education is a deal with future, and this is true for Rousseau, too. The ages of childhood of youth are clearly defined, so are the phases of education, nature is not chance but necessity, aiming at the future. Children should be educated solely dependent on *things* (Rousseau, 1969: p. 311), nevertheless the governor dominates the whole education. Nature should lead the way (Rousseau, 1969: p. 259), but everything possible must be taken to avoid the first wrong step (Rousseau, 1969: p. 317). Children stand like savages outside the law and are completely natural (Rousseau, 1969: p. 320), but education must undertake everything so as to *exclude* chance (Rousseau, 1969: p. 342) without being able to act *solely* to the necessity of nature. The first education should be that of the *senses* alone (Rousseau, 1969: p. 380), but that requires a rational plan of education that cannot simply be drawn from nature. And in consequence, Rousseau's educational scene is one of extreme regulations: Emile does not play, he does not develop any form of his own, and is not allowed to listen to music, his learning differs in every way to 'amusement' (Rousseau, 1969: p. 407), education should be 'realistic' (Rousseau, 1969: p. 418), and this is possible only in an extremely artificial manner. Because society is excluded educational rigorism can rule. The basis for this is *nature* in the sense of *self-love* (amour de soi). Self-love is always good and always in compliance with the natural order (Rousseau, 1969: p. 491), which begs the question why education does not concentrate fully on this *amour de soi*.

Rousseau wrote the counterproject to sensualistic educational theory, which dominated the pedagogy of the eighteenth century. Children, according to Rousseau, should not be viewed as empty vessels or *tabula rasa*, but instead as part of nature, which develops of its own accord. It cannot simply be influenced, education is not merely the establishment of habits and customs, moreover it is the child's nature that limits all education. This fundamental concept is weakened by the *implicit* sensualism, the education of the senses (Rousseau, 1969: pp. 415 et seq.), that is necessary, because education is inconceivable *without any* influence. But the provocation remains, and it defines Rousseau's standing as an educational author. Education is limited by nature, nature has nothing to do with sin, the child is innocent because of nature's original goodness, thus education can take place without any burdens of history and society. It is a renewal of mankind with every new child. This is the peak or the basic point of Rousseau's theory, which is read up to now because it provocates *and* stimulates educational thought, without any attempt to solve

the puzzles. Rousseau is read because he defines the problems, not the solutions.

Routine Activities, Criminal Opportunities, Crime and Crime Prevention

Abstract

A theoretical framework focused on crime as a function of situation-specific opportunity emerged in the field of criminology in the latter part of the twentieth century. This framework consists of several overlapping yet distinct theories, including routine activities theory. Though routine activities theory is perhaps most notable, a number of other perspectives emphasizing situational opportunity were developed around the same time as the initial explication of routine activities theory. Today, the overlap in these distinct theoretical statements is widely recognized, and they are thus increasingly treated in an integrative fashion, so as to create a more general crime opportunity perspective.

Criminology is largely focused on understanding why it is that some people – whether as individuals or as aggregates – are more likely to break the law than other people. In other words, criminologists have long sought to explain differences in propensity for law-violating behavior, often referred to as criminality. However, a subset of criminologists have reoriented scholarship away from trying to understand criminality and toward an understanding of crime events instead. They note that for a crime event to take place, offenders must have more than criminality; they must also have the opportunity to act on their desires.

This 'opportunity perspective' of crime events emerged in the field of criminology around 1980, and it now consists of several overlapping yet distinct theories. Though initially viewed as outside the mainstream of criminological theory, the opportunity perspective has since gained many followers, and it is now considered a major paradigm in the field. This article elaborates on the development of the crime opportunity perspective. This description begins with an explanation of routine activities theory, arguably the most important theory comprising the opportunity perspective.

Routine Activities and Crime

Though crime long has been a social concern in the United States, public and scholarly concern over the crime problem was clearly justified in the 1970s and 1980s. Historical trends of national crime data show that there were unprecedented increases between 1960 and 1970, in particular, with rates still climbing, albeit less dramatically, up to 1980. But what were the social changes that were behind these trends? Accounting for the unprecedented increase, nationally, was the starting point for a series of articles published by University of Illinois colleagues Lawrence Cohen, Marcus Felson, and Kenneth Land during the late 1970s and through the 1980s. (Marcus Felson left Illinois for University of Southern California in 1984. He was there until 1995, when he joined the faculty in the School of Criminal Justice at Rutgers University. Most recently, he joined the faculty at Texas State University. Kenneth Land departed University of Illinois for University of Texas's Department of Sociology, where he was on faculty from 1981 to 1985. In 1986, he then moved to the Department of Sociology at Duke University, where he remains today. Lawrence Cohen also left University of Illinois for University of Texas. He subsequently joined the sociology faculty at University of California–Davis.)

This team of researchers rejected the prevailing theories of the day as possible explanations for the historical, national-level trends, they were observing in the time series spanning from the late 1940s to the mid-1970s. For instance, they eschewed the notion that the dramatic increases could be attributed to economic deprivation, which was often depicted as the culprit. In fact, they identified a 'sociological paradox' in the examination of trends in economic conditions in the United States vis-à-vis trends in crime. During the 1960s, household income increased, and the disparity between white and black household incomes declined; the percentage of urban residents living in poverty decreased; unemployment decreased; and median education level increased, especially among blacks (Cohen and Felson, 1979). Yet, between 1960 and 1975, robbery rates increased by 263%; aggravated assault, rape, and homicide increased between 164 and 188%; and burglary increased by 200% (Cohen and Felson, 1979).

In 1979, Cohen and Felson published the seminal article in the American Sociological Review, *Social Change and Crime Rate Trends: A Routine Activity Approach*. It was the first in a series of articles to be published by the team of Cohen, Felson, and Land. In that article, Cohen and Felson addressed the paradox as follows:

> Why, we must ask, have urban violent crime rates increased substantially during the past decade when the conditions that are supposed to cause violent crime have not worsened – have, indeed, generally improved?…we consider these paradoxical trends in crime rates in terms of the changes in the "routine activities" of everyday life. We believe the structure of such activities affects criminal opportunity….
>
> (Cohen and Felson, 1979: pp. 588–589)

The Minimal Elements of Crime

As a starting point for explaining how routine activities produce criminal activity, Cohen and Felson enumerated three minimal elements for a crime event (see also Cohen et al., 1980, 1981;

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45080-4

Felson and Cohen, 1980; Felson, 1987, 1994). Though inclination to offend (the focus of traditional criminological approaches) is one of these elements, the mere presence of an offender is not enough for a crime event. If a motivated offender does not encounter a suitable victim or target, a crime event cannot occur. Or, if a potentially suitable victim or target do meet, but there is someone or something present that is capable of intervening or preventing the crime, then a crime event cannot occur. Thus, at minimum, a crime event needs the following:

1. a motivated offender – someone inclined, willing, and able to commit the crime;
2. a suitable victim or target – a person or thing that allows the offender to fulfill criminal objectives; and
3. absence of capable guardianship – any persons or things that can discourage/prevent the crime.

Cohen, Felson, Land, and colleagues stressed that these three minimal elements must converge in a place/time context or spatiotemporal setting. There is not criminal opportunity without a motivated offender converging in place and time with a suitable victim or target and absence of capable guardianship.

The Role of Routine Activities

Cohen, Felson, Land, and colleagues presumed that the convergence in time and space of the three ingredients for crime was affected by the patterns of activity comprising everyday life. Activities outside the home were seen as particularly opportunistic. Going to school, to work, to shop, to dine out, or to be entertained – these are all legitimate, public activities comprising everyday life. Yet, these legal, routine activities were presumed to have consequences for illegal activities, nonetheless, because they affect criminal opportunity. More specifically, these activities affect both the supply of suitable victims or targets available to motivated offenders and the level of guardianship provided to those victims/targets. As such, they affect the extent to which there will be spatiotemporal convergence of motivated offenders and suitable targets in the absence of capable guardianship. In short, criminal and noncriminal activities are presumed to be interdependent.

As an example of how legitimate activities feed illegitimate activities, Cohen, Felson, Land, and colleagues posited that the dramatic rise in crime witnessed in the United States between 1960 and 1970 was a result of profound changes in the routine, daily activities of its residents. The change in routine activities increased the overall supply of suitable targets with ineffective guardianship, thereby increasing criminal opportunity. But how, specifically, were American activities changing, beginning in 1960, so as to affect criminal opportunity? The short answer to the question was that Americans were engaging in many more nonhousehold activities. Simply put, with more Americans engaging in activities outside the home, they were more accessible to motivated offenders, and they and their property were less effectively guarded. Substantial increases in college attendance and labor force participation among women between 1960 and 1970 was responsible for a large share of the overall shift in Americans' activities. Women's pursuit of post-secondary education and work outside the home increased their public exposure, thereby also enhancing the pool of available, suitable targets for predatory crimes like robbery and sexual assault. At the same time, less guardianship was being provided to American households during the daytime, thereby increasing opportunity for crimes such as burglary. For instance, in 1960, about 30% of households were unoccupied by someone 14 years or older between the hours of 8 a.m. and 3 p.m.; by 1971, that figure exceeded 40% (e.g., Cohen and Felson, 1979).

The time period between 1960 and 1970 saw shifts in activities beyond the realms of school and work. Shifts in education- and employment-related routines of women had the effect of generating more disposable income for American households – income which was channeled toward more leisure pursuits outside the home (i.e., attending sporting events, movies, restaurants, or vacation destinations) and the purchase of more household durable goods (i.e., televisions, stereos, cars, and bicycles). This proliferation of public leisure activities and household items (especially valuable but lightweight items) served to increase opportunities for crime. Thus, the overall crux of the explanation offered by routine activities theory for the large uptick in crime after 1960 (especially between 1960 and 1970) was that motivated offenders were increasingly likely to encounter people with money and other valuables on their person and/or encounter an empty house with plentiful goods for the taking.

Cohen and Felson (1979) first tested routine activities theory in their 1979 article by examining whether a 'household activity ratio' was related to the changing rates of predatory crime in the United States between the years 1947 and 1974. They measured the household activity ratio as the proportion of US households that were either 'non-husband-wife' households or households that could be classified as "married, husband-present, with a female labor-force participant" (Cohen and Felson, 1979: p. 600). They surmised that these household structures were likely to engage in public activities that would increase exposure to motivated offenders, increase target suitability, and decrease guardianship. They found that the household activity ratio was, in fact, positively and significantly associated with five different types of predatory crime rates. In a follow-up article, 1 year later, Cohen et al. (1980) also found that consumer expenditures on durable goods (nonautomobile) were positively related to 25-year trends in US burglary rates.

In short, Cohen, Felson, and Land put forth a theory that challenged conventional way of thinking about crime as a pathology that emerged from social ills. Their challenge was particularly interesting given the social and political context of the 1970s. This was a time of unprecedented change. It was not just that crime was rising; there were riots in the inner cities and protests were abundant. In response, presidential crime commissions were formed, and there were conservative calls for law and order (e.g., Wilson, 1975). It was natural that everyone was worried about the 'bad things' happening in society. But Cohen, Felson, and Land took a step back and boldly presented an alternative view that 'good things' were causing fluctuations in crime.

Lifestyle, Exposure, and Criminal Victimization

The year before Cohen, Felson, Land, and colleagues began publishing numerous works on the influence of routine activities on temporal trends in US crime, a similar idea had been put forth as a way to understand variation in victimization risk across demographic subgroups by a group of criminal justice scholars at State University of New York at Albany. In the 1970s and 1980s, the Criminal Justice Research Center at Albany, under the founding directorship of Michael Hindelang, was engaged in analyses of (then-new) national victimization survey data (from the National Crime Survey, now called the National Crime and Victimization Survey). The analyses they provided of victimization data were transformative for a field that had historically relied upon official police reports for the measurement of crime. Yet, the National Crime Survey data did more than provide an alternative aggregate measure of crime in the United States. It also provided a mechanism for understanding the victim's role in crime occurrences.

One particularly influential product of the Albany-based analysis of the National Crime Survey was the 1978 book, *Victims of Personal Crime: An Empirical Foundation for a Theory of Personal Victimization* by Michael Hindelang, Michael Gottfredson, and James Garofalo. The crux of this work was the suggestion that victimization risk was partly a function of lifestyle. Their argument was that demographic groups experiencing relatively higher rates of victimization – men, younger adults, and African-Americans, in particular – tended to have lifestyles that exposed them to victimization opportunities. In particular, Hindelang et al. (1978) posited that the lifestyles of these high-risk demographic groups, relative to low-risk demographic groups (i.e., women, the elderly, whites), involved more time in public (especially at night), more time away from family or household members, and greater proximity to and/or association with high-offending groups. This idea was termed the 'lifestyle–exposure theory' of victimization.

The theoretical overlap between lifestyle–exposure theory and routine activities theory is evident. Lifestyle–exposure theory was originally developed as a way to understand variation in victimization risk across different demographic groups in the United States, whereas routine activities theory was posited as a way to understand temporal patterns in national-level crime rates. While they developed independently, and within the context of very different academic departments and research programs, both stressed that lifestyles and daily activities affected opportunities for crime/victimization events. Taken together, these perspectives suggested that lifestyles and activities, and the opportunities for crime that they created, varied across demographic groups and spatiotemporal context. Given the similarity and compatibility among these perspectives, they were eventually merged into a more general 'lifestyle–routine activities theory' (L-RAT) (e.g., Cohen et al., 1981; Miethe et al., 1987). By the 1990s, L-RAT had become a popular approach for understanding individual variation in victimization risk, in particular (e.g., Miethe and Meier, 1994; Miethe and McDowall, 1993; Fisher et al., 1998; Mustaine and Tewksbury, 1998; Schwartz and Pitts, 1995; Wilcox Rountree et al., 1994).

Routine Activities and Offender Searches: Crime at Specific Nodes, Paths, and Edges

Around the same time that Cohen, Felson, and Land were developing routine activities theory and Hindelang, Gottfreson, and Garofalo were explicating a lifestyle–exposure theory of victimization, a pair of criminologists working in Canada were also thinking about crime in terms of opportunity as opposed to motivation. Paul and Patricia Brantingham edited their seminal book *Environmental Criminology* in 1981. It offered a view of how offenders searched for targets, with the result of their searches being discernible, nonrandom patterning of crime (creating hot spots) within communities. Their work suggested that targets were chosen through purposeful search, in an attempt to balance issues of effort, risk, and profit. As such, targets that were easily accessible, vulnerable, and valuable were most often sought by offenders. However, the Brantinghams recognized that the target selection decision was also hierarchical or multistaged. In other words, before certain targets are selected, a general area (i.e., community) within the offender's activity space was chosen (Brantingham and Brantingham, 1981, 1993; see also Taylor and Gottfredson, 1986). In this way, offenders have been described as foragers, who "must find a good hunting ground before starting to chase prey" (Bernasco and Block, 2009: p. 96; see also Bernasco and Nieuwbeerta, 2005; Coupe and Blake, 2006; Felson, 2006). Thus, environments in which specific targets are located – not just the specific targets themselves – are key in providing criminal opportunity to offenders. Simply, places vary in terms of their suitability for offenders' target searches.

What sorts of places are perceived by offenders as advantageous hunting grounds? The Brantinghams suggest that offenders will find their targets within the geographic space where they carry out their routine activities; they refer to this area as an offender's 'activity space' (e.g., see Brantingham and Brantingham, 1981, 1993, 1995). Specifically, offenders are likely to choose attractive targets at or near the places where they conduct their routine activity. These activity nodes include schools, workplaces, shopping or entertainment areas, and more generally, areas near offenders' residences. Motivated offenders can readily come into contact with suitable targets at such nodes. Hence, activity nodes generate plentiful opportunities for crime. Major routes (streets, walkways, etc.) that surround and connect various nodes also provide numerous targets for offenders searching for crime. These major routes, which the Brantinghams refer to as 'paths,' are therefore likely to host higher than average crime events. Some central nodes and pathways will generate so much opportunity that they might actually become 'crime attractors' – places that offenders travel to specifically for crime purposes.

The Brantinghams also suggested that offenders often find targets in their search for crime, not only at major nodes and paths within their activity spaces but also at 'edge space' (Brantingham and Brantingham, 1981, 1993, 1995). According to the Brantinghams, edge spaces are boundary areas, which form the transition from one distinct physical space to another. Given their transitional nature, there are sometimes multiple users of edge spaces; those who use each

space often converge at the edges, creating a 'crossover' of users. This crossover provides an abundance of targets for offenders. At the same time, there is often ambiguity in terms of who 'owns' and thus controls edge space, thus diminishing guardianship.

Crime and Place Research

Several scientific lines of inquiry have supported the idea, emerging from the Brantinghams' work, that crime is particularly plentiful at major nodes, in particular. For instance, beginning in the 1980s, Dennis Roncek and his colleagues published a series of studies highlighting how streets with nonresidential land uses had heightened crime risk (Roncek and Bell, 1981; Roncek and Faggiani, 1985; Roncek and LoBosco, 1983; Roncek and Maier, 1991). Specifically, their work showed that presence of on-premise alcohol outlets and high schools were positively related to crime on street blocks. These establishments were presumed to generate crime on the blocks containing them by increasing population density, even if the density was ephemeral (i.e., due to nonresidents visiting at particular times of day). Such high-density land uses – which attracted teenage and young adult users and/or users under the influence of alcohol – were particularly conducive to a convergence of motivated offenders and suitable, unguarded targets. Contemporary research since Roncek's pathbreaking work continues to support the idea that street blocks or block groups with more nonresidential land uses experience higher rates of crime (Kurtz et al., 1998; LaGrange, 1999; Rice and Smith, 2002; Smith et al., 2000).

The classic study on crime 'hot spots' by Sherman et al. (1989) also supports the Brantinghams' theoretical ideas. Sherman et al. analyzed all calls for service for 1 year in Minneapolis. These crimes could have potentially occurred at 115 000 different 'places' (i.e., addresses or intersections) within the city. However, their analysis of the calls revealed that most places experienced no crime. Instead, crime tended to cluster nonrandomly in just a few 'hot spots' with repeat crime problems. In fact, fully 50% of all crimes in the city occurred at just 3% of the places throughout the city. Among the identified 'hot spots' were nodes such as department stores, bars, and convenience stores. Subsequent work by David Weisburd and his colleagues has shown similar patterns of hot spot concentration in Seattle, with crime clustering nonrandomly on certain street segments and largely remaining stable in this patterns of clustering over time (Groff et al., 2010; Weisburd et al., 2004, 2012). This group's work has emphasized the clustering of crime at nodes and along major paths; streets segments which are arterial roads (paths), bus routes (paths), and near public facilities (nodes) are among those with heightened likelihood of being chronic crime hot spots as opposed to crime-free street segments. Recent work has shown similar crime clustering in other cities (e.g., Bernasco and Block, 2011; Braga et al., 2011).

In sum, routine activities theory was initially tested at the national level with time series data on US crime rates. The theory was subsequently integrated with lifestyle–exposure theory and applied at the individual level in order to account for variation in victimization risk. Most recently, it has been integrated with theory on offender search patterns and applied to microspatial units such as places and street segments in order to help understand crime hot spots.

Environmental Design and Crime

Alongside the development of lifestyle–routine activities theory in the 1970s and 1980s was a theoretical and empirical line of inquiry stressing the idea that a community's physical design – its 'built environment' – played a major role in the opportunities for crime therein. The origins of the focus on the relationship between environmental design and crime can be traced to influential, overlapping works by Jane Jacobs (1961), Elizabeth Wood (1961), C. Ray Jeffrey (1971), and Oscar Newman (1972). Oscar Newman's book, *Defensible Space: Crime Prevention through Urban Design*, was particularly useful in articulating an explicit theory of crime (and the prevention thereof).

His famous work, *Defensible Space*, was a study of urban residential housing communities, the various physical forms they take, and the implications of those forms for crime rates within. In contrast to the high-rise public housing developments, Newman noted that low-income residential communities that consisted of low-rise 'walk-up' style housing (i.e., townhouse style) tended to have few problems. Since social characteristics of residents were similar across many of the high- and low-rise public housing communities he observed, he claimed that differences in physical designs were behind differences in crime and other social ills across the developments. According to Newman, the physical layout of the low-rise walk-ups allowed the space to be more easily defended or controlled by residents. In short, the low-rise style housing communities had defensible space. Newman elaborated that defensible space was related to four principles: territoriality, natural surveillance, image, and milieu.

Newman defined territoriality as "the capacity of the physical environment to create perceived zones of territorial influences" (Newman, 1972: p. 51). In other words, territoriality is the extent to which a space conveys a sense of being 'owned' or 'private' and as having clearly designated purposes (i.e., people have a clear sense of how and when to use the space) through use of boundary markers, signs, and other visual cues. Natural surveillance referred to "the capacity of physical design to provide surveillance opportunities for residents and their agents" (Newman, 1972: p. 78). The height of buildings, the placement of buildings vis-à-vis the street and other buildings, the number of access routes in and out of an area, the height and placement of shrubbery or trees, and the presence or absence of alcoves, niches, or alleyways are examples of physical design features that affect the potential for resident-based surveillance. "Image" was defined by Newman as "the capacity of design to influence the perception of an area as unique, well-maintained, and non-isolated" (Newman, 1972: p. 102). The use of unique designs and distinctive materials in the building of a space, as well as the upkeep and maintenance of the space, conveys the message that the area is being cared for, thus deterring incivility and making it

more easily defended. Poorly maintained spaces, on the other hand, generate a negative type of distinctiveness – a negative stigma that can attract offenders. Also related to image is 'milieu,' or the location of the space within the broader urban locale. Spaces adjacent to risky places can experience 'spillover'.

Overall, then, Newman suggested that spaces which provided territoriality, natural surveillance, positive image, and 'safe' adjacency would be more easily defended by residents. His theory, therefore, assumed that the physical environment was important because of how it affected the social control exerted within. Newman, in fact, defined defensible space as "a model for residential environments which inhibits crime by creating the physical expression of a social fabric that defends itself" (Newman, 1972: p. 3). He saw territorial behavior – inhabitants taking primary responsibility for controlling behavior – as a latent characteristic of small communities, like public housing projects. This latent territorial behavior only needed to be fostered through smart physical design.

Crime Prevention through Environmental Design

Newman's idea that physical design affected crime through prompting resident-based territorial attitudes and behavior was influential yet unpopular among some. Critics provided evidence that 'defensible' physical design did not necessarily affect the willingness of residents of an area to engage in social control (e.g., Donnelly and Kimble, 1997; Merry, 1981). However, many aspects of Newman's work were lasting. In particular, it fostered a movement that focused on the idea that physical design of spaces can affect the opportunity for crime, regardless of whether resident-based territorial attitudes or behaviors are affected and therefore can be manipulated for prevention purposes. This alternative conceptualization of the role of physical design is referred to as Crime prevention through environmental design (CPTED) and it is popular in a variety of settings today (e.g., see Crowe, 2000).

CPTED posits that aspects of physical space – such as an area's accessibility, surveillance potential, management or ownership, and level of support offered for legitimate activities – should affect crime by impacting the costs versus benefits of crime available to offenders. A number of studies over the past three decades have shown support for the importance of physical design features that affect surveillance, in particular. For instance, number of access routes, traffic volume, presence of escape routes (i.e., proximity to highway), and obstacles to surveillance within a neighborhood are positively related to rates of crime (Bernasco and Luykx, 2003; Greenberg et al., 1982; Taylor and Harrell, 1996; White, 1990).

Offender Decision Making and Crime Patterns

Around the same time that routine activities theory, lifestyle–exposure theory, offender search theory, and environmental design theory were being developed, Ronald Clarke, in collaboration with Derek Cornish, was defining a contemporary rational choice theory of offending. This theory, like the aforementioned theories, highlighted the importance of criminal opportunity.

A seminal 1985 book chapter by Clarke and Cornish, *Modeling Offenders' Decisions: A Framework for Research and Policy*, was particularly key in defining their perspective. In this piece, they provided a framework countering positivist theories of crime which posited that criminal behavior was caused or determined by distinct biological, psychological, or social characteristics. Rather, Clarke and Cornish suggested that offenders make active, utilitarian decisions about alternative lines of action, including crime, through a process of 'bounded rationality'. In other words, offenders were thought to actively weigh the costs and benefits of alternative lines of action (i.e., crime versus legitimate alternatives), though it was recognized that their perceptions of costs versus benefits were likely shaped by biological, psychological, and social 'background factors, previous experiences, immediate needs or pressures, and so on. Thus, criminal choices may not be optimal, but to Clarke and Cornish, they represented offenders' best efforts at optimizing outcomes (Clarke and Cornish, 1985: pp. 163–164; see also Shover, 1996). Regardless of the many factors shaping an offender's perceptions of cost versus benefit associated with criminal action, such action is still ultimately presumed to be based on the utilitarian pursuit of pleasure over pain according to Clarke and Cornish's perspective.

Clarke and Cornish delineate two major types of decisions made by offenders: crime involvement decisions and crime event decisions. A crime involvement decision refers to the offender's choice that crime is an acceptable line of action. Event decisions consist of the choices that are made in actually carrying out an offense. For instance, decisions about where to offend (area selection), against whom or what to offend (target selection), and how to offend (modus operandi) are event decisions. Event decision making, in particular, is presumed to involve offenders making reasoned choices – choices about the particular ecological settings within which they will offend and the particular targets they will select. Choices about settings and targets are thought to be based on environmental cues regarding risk, reward, and effort (e.g., Clarke, 1980; Clarke and Cornish, 1985). In other words, criminal opportunity weighs heavily in choices during crime events according to Clarke and Cornish's rational choice perspective.

Integrated Perspectives

All perspectives discussed up to this point in the article emphasize 'criminal opportunity' as key in understanding offender decisions and the resulting spatiotemporal clustering of crime. The various perspectives assume that offenders make conscious decisions, albeit sometimes severely constrained, about their crime events. Collectively, they implicate as key various features of the crime setting but are united in the underlying principle that crime is ecologically rooted. Though overlapping and conceptually compatible, these various perspectives have largely developed independent of one another and have traditionally been treated by most scholars

as rather disparate. However, that trend has been changing with the development of integrative approaches.

The 25 Techniques of Situational Crime Prevention

Perhaps the most widely known integrative approach to understanding the myriad environmentally based sources of criminal opportunity comes from Ronald Clarke and various colleagues who have, over the last few decades, developed an explicit approach to reducing crime at particular spatial locations. Their approach – termed situational crime prevention (SCP) – builds directly on Clarke and Cornish's Rational Choice Theory in that it assumes that offenders make choices about committing crime at particular places using utilitarian principles. Specifically, SCP suggests that the concepts of effort, risk, reward, provocation, and excuses provide a framework for understanding the decisions of offenders. Offenders are likely to choose to commit a particular crime at a particular location if the crime is easy to commit, if it is low risk and high reward, if there are situational provocations, and if there are available excuses provided by the environmental setting. Thus, in order to prevent future crime at hot spots, steps can be taken to change the environment in which the crime is repeatedly occurring such that the effort required on the part of offenders is enhanced, risk is increased, rewards are lessened, provocations are reduced and excuses are removed (see, e.g., Cornish and Clarke, 2003; Smith and Clarke, 2012).

Specific techniques offered by Cornish and Clarke for crime reduction are based on their elaboration of the situational factors affecting offender's perceptions of effort, risk, reward, provocation, and excuses. The situational factors they identify appear to draw upon the theories discussed above, including routine activities theory and environmental design theory. For instance, perceived effort is influenced by whether a potential target is 'hardened' (i.e., protected), by whether the location in which the target is situated can be accessed by the offender, by whether the location in which the target is located can be exited (by the offender) without difficulty or obstacle, and by whether any tools or weaponry necessary for committing a crime are available to the offender. An offender's perception of risk is likely influenced by such things as the amount of guardianship provided to specific targets, the amount of natural surveillance available in the environment in which the target and offender are located, and the amount of both informal and formal surveillance and control exerted within the environment in which the target and offender are located. Perception of reward is influenced by factors such as the level of visibility and portability of targets, the extent to which targets can be traced, and the availability of markets that allow offenders to move stolen merchandise. Provocations can be influenced by environmental conditions that incite anxiety, foster disputes, or encourage boundary testing. Such conditions include extreme noise, overcrowding, rivals within close proximity (i.e., rival sports fans watching 'the big game' at the same bar), disorder, and peer pressure. Finally, offenders may perceive excuses for crime in settings in which, for example, rules are ambiguous, behavioral instructions are not evident, or where compliance is not facilitated.

Thus, conceptual integration is inherent in theory behind the techniques of SCP; overlapping constructs from previously disparate perspectives are woven together and used to understand how offenders perceive opportunity and, in turn, how we might reduce opportunity. While conceptually integrative, those practicing SCP have really shied away from integration across multiple contexts and have instead emphasized opportunity and its reduction at one primary unit of analysis – the immediate, microspatial setting in which repeated crime events are occurring. However, as discussed more fully below, recent theoretical work has suggested that situational prevention is perhaps optimally applied simultaneously to multiple embedded contexts.

Multilevel Opportunity Theory

A general, multilevel opportunity perspective emphasizes that opportunity stems from multiple, overlapping theoretical processes and opportunity is structured at multiple, embedded levels of analysis (Wilcox et al., 2003; Wilcox et al., 2013). For example, a multilevel perspective on opportunity stresses the importance of recognizing that crime is patterned nonrandomly across multiple levels of analysis, including individuals, places, streets (or street segments), neighborhoods, and the like. These various levels represent unique types of behavior settings and, as such, they have distinct structures of opportunity (Taylor and Gottfredson, 1986; Taylor, 1998). The various levels/settings and their respective opportunity structures – additively and in interaction with one another – can affect the spatial patterning of crime that we see at various levels of analysis.

As an example of a general, multilevel opportunity theory, Wilcox et al. (2003) conceptualized and operationalized opportunity at multiple levels. They drew upon routine activities theory most directly, suggesting the opportunity was a function of three major factors: (1) exposure to motivated offenders, (2) target suitability, and (3) absence of capable guardianship. However, they suggested that these three factors not only emerged from routine activities but also were affected by environmental design and various facets of social control (including social bonds/handles, social disorganization, and deterrence). In addition to conceptualizing opportunity by integrating concepts from various opportunity theories, Wilcox et al. (2003) suggested that opportunity existed at both individual and environmental levels, with 'environmental' potentially referring to streets, schools, neighborhoods, or broader areas. Finally, they suggested that individual-level and environmental-level indicators of opportunity could interact.

There is mounting empirical evidence that the tenets of a general, multilevel opportunity theory – such as that posited by Wilcox et al. (2003) – have merit (for a recent review, see Wilcox et al., 2013). For instance, there are now a number of multilevel studies of victimization which, collectively, promote the idea that characteristics associated with routine activities, environmental design, and social control at individual/household and neighborhood levels of analysis impact victimization risk (e.g., Kennedy and Forde, 1990; Sampson and Wooldredge, 1987; Smith and Jarjoura,

1989). Furthermore, a number of the multilevel studies show that victimization risk is affected by the interaction between individual- and neighborhood-level indicators of opportunity (Miethe and McDowall, 1993; Wilcox et al., 2007; Wilcox Rountree et al., 1994).

Conclusion

Routine activities theory is perhaps the most noted criminological perspective emphasizing crime opportunity as a key theoretical construct. However, a number of other perspectives emphasizing the importance of opportunity were being developed by various groups of scholars in different parts of the world around the same time as routine activities theory. Over the course of the past several decades, these overlapping perspectives have coalesced to form a more overarching, general opportunity perspective on crime.

Rule of Law (and Rechtsstaat)

Martin Krygier, University of New South Wales, Sydney, NSW, Australia; and Regulatory Institutions Network, Australian National University, Acton, ACT, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In all its many versions, the rule of law has to do with the relationship between law and the exercise of power, particularly public power. As an ideal, it signals that law can and does well to contribute to articulating, channeling, constraining, and informing – rather than merely serving – such exercise. Beyond that, what it rules out, what it allows, what it depends on, and indeed what it is, are all matters of disagreements that stem from differences among political and legal histories and traditions, and reflect dilemmas and choices that recur, in different forms and weights, in many such histories and traditions. This article is concerned with these enduring themes, dilemmas, and choices, as they occur within particular traditions, especially the common law 'rule of law' tradition, on the one hand, and the Continental Rechtsstaat tradition, on the other.

From the last quarter of the twentieth century, the rule of law has come to occupy an increasing amount of discursive space, not only among lawyers, for whom it had been an old theme, but also among promoters of economic development, human rights, democratization, state building, and political and legal reform. Increasingly, it is alleged, the rule of law is a key ingredient in the attainment of all these good things and others. As one author has observed,

> Among a plethora of development and security agencies, a new "rule of law consensus" has emerged. This consensus consists of two elements: (1) the belief that the rule of law is essential to virtually every Western liberal foreign policy goal – human rights, democracy, economic and political stability, international security from terrorist and other transnational threats, and transnational free trade and investment; and (2) the belief that international interventions, be they through money, people, or ideas, must include a rule-of-law component. (Call, 2007: p. 4)

In this transformation, the rule of law has gained a great deal in modishness but less, actually nothing, in clarity. But clarity was never the concept's strong suit. Like many other important moral, political, and legal ideals, among them democracy, justice, and liberty, its meaning, scope, conditions, and significance are all highly, perhaps essentially, contested (Waldron, 2002). And like those ideals, not only are there enduring common themes but also common axes of argument and disputation that pervade discourse on the rule of law. As suggested elsewhere (Krygier, 2011: p. 69), these contests do not render such concepts meaningless or useless. On the contrary, some of them are the most important we have. We will not resolve those contests, here or anywhere, but it might be possible to clarify a few of them and suggest why they – and the rule of law – are important.

The concept of the rule of law embodies ideals that have figured in political and constitutional discourse at least since Aristotle, who contrasted 'the rule of the law' with 'that of any individual.' Those ideals have varied, so too the strategies to achieve them and the verbal formulation of them. They revolve around enduring themes and concerns; however, the character of which is nicely captured by Otto Kirchheimer's laconic observation that:

> for all the differences in historical roots and particular legal traditions their common denominator lies in the simple thought that the security of the individual is better served when specific claims can be addressed to institutions counting rules and permanency among their stock-in-trade than by reliance on transitory personal relations and situations. Beyond that, a good part of their common success probably lies in the mixture of implied promise and convenient vagueness. (Kirchheimer, 1992; first published 1967: p. 244)

In all versions, the rule of law has to do with the relationship between law and the exercise of power, particularly public power. As an ideal, it signals that law can and does well to contribute to articulating, channeling, constraining, and informing – rather than merely serving – such exercise. That takes us some distance from those who see law simply as one of the means by which power is exercised, neither better nor worse than any other. For there are lots of ways to exercise power; partisans of the rule of law insist that it helps us block some of them, including many of the worst of them (see Rundle, 2009), and to channel others in salutary directions and ways. But what it rules out, what it allows, what it depends on and indeed what it is, are all matters of disagreement. This is so for several reasons, often stemming from differences among political and legal histories and traditions, and reflecting dilemmas and choices that recur, in different forms and weights, in many such histories and traditions.

Law and State

These days, and in contemporary language, the words 'law' and 'state' are rarely far apart. However, it was not always and everywhere so, and even now it makes a difference whether the connection is seen as necessary or contingent, even more so whether it is seen as a conceptual rather than an historical connection. A clue to this comes from the terms used in various languages. In particular, there is an obvious semantic difference between 'rule of law,' the term used in English, and those found

in many European languages to cover some, but not all, of the same terrain. Each of these has a context and a history that cannot be ignored or simply elided, but in a host of European languages there is one thing commonly built into the concept, which is missing from the English phrase: the State. Whether it is *Rechtsstaat* (German: state of law; law-governed state), *état de droit* (French), *statto diritto* (Italian), *estado de derecho* (Spanish), *państwo prawa* (Polish), or *pravovoe gosudarstvo* (Russian), law is inextricably connected to the state. It is the subject – grammatically and ontologically – of each rendition. However, unlike all these terms, the rule of law does not mention the state. This is not an accident.

The concept of the state is not part of English constitutional jurisprudence, while in Australia and the United States it refers to what Germans would call *Länder* (see MacCormick, 1984: p. 65). More deeply, the English tradition was long pluralistic in its conceptions of the sources of law (Rosenfeld, 2001), with multiple cumulative and competing authoritative sources, among them custom, court decisions and statutes. Indeed, while the common law courts were long agents of the Crown, some of the mythologically most powerful contests in the English rule of law tradition, particularly the constitutional struggles of the seventeenth century, pitted them against successive wearers of that Crown, even at the cost of the head of one of those (Charles I), what might in other countries be called the head of State.

According to the common law tradition, popular custom, an "ancient collection of unwritten maxims and customs" (Blackstone [1765–69] 1979, vol. 1: p. 17) was long seen as a primary source of law, and "[t]he only method of proving, that this or that maxim is a rule of the common law, is by showing that it hath been always the custom to observe it" (Blackstone [1765–69] 1979, vol. 1: p. 68). That custom was evidenced (rather than made, it was claimed) by another nonlegislative source, the judgments of courts in particular cases brought to them. This was the 'common law' (Krygier, 1998), which seventeenth-century partisans of the rule of law preferred to the commands of the King; "Law established by customary practice, law that was not the creation of will, command, or sovereignty, was a restraint on government – a restraint on discretionary power" (Reid, 2004: p. 12). True, the courts were the King's courts, but the law they adjudicated was not, in the main, considered to be the King's creation. It was not just an instrument with which the Crown and the state could direct activities and control public policy. For the King, like his subjects, was subject to 'the law of the land.'

Deliberate, secular, purpose-guided, prosaic (not sacred) legislation, as Max Weber observed, is a central and distinctive characteristic of modernity in law (see Weber, 1968: pp. 760–768). Today, of course, in its exponential rush since the eighteenth century (see Lieberman, 1989), legislation has swamped custom and even judicial decisions as a quantitatively primary and increasingly imperious source of law, in the common law world as elsewhere. However, the notion that the rule of law draws upon sources other than legislative fiat (i.e., an order for an act to be carried out), that the judiciary is a fundamental guardian of it, and that all, even the most powerful, are and should be subject to it, goes deep in the common law tradition and has not lost resonance. It was expressed in many ways over centuries, but the canonical connection between the term 'rule of law' and those thoughts came to displace other descriptors, primarily as a result of the hugely influential late nineteenth century work by A.V. Dicey (Dicey, 1961 (first published 1885)). Dicey's formulations distilled (and in some respects distorted) a very old English legal tradition.

No parallel existed in the nineteenth and early twentieth century *Rechtsstaat*. The term was coined only at the very end of the eighteenth century (Heuschling, 2002: p. 29), to capture a new phenomenon, the modern State with its monopoly of force. That state was the subject of this concept, and also the legal source of law. The *Rechtsstaat* ruled *by or through* law, whereas other states, such as the *Machtstaat* (power-governed state) or *Polizeistaat* (police-governed state) (see Raeff, 1983) might dispense with it and exercise power in other ways. What was distinctive of a *Rechtsstaat* was not that the state was subject to law that had other sources and independent guardians, but that it acts in a *rechtlich* (lawful, legal) way; "according to some nineteenth century (and early twentieth century) constructions, there is a relation of near-identity between the state and its law … within the system of rule the law is the state's standard mode of expression, its very language, the essential medium of its activity" (Poggi, 1978: p. 102). That is how we recognize it as a *Rechtsstaat*, as distinct from any other type of state. There was no conceptual space to say to the State what Sir Henry Bracton already said in the thirteenth century:

> The king has a superior, namely God. Also the law by which he is made king. Also his *curia*, namely the earls and barons, because if he is without bridle, that is without law, they ought to put the bridle upon him. (quoted in Reid, 2004: p. 11, and see Palombella, 2010; *passim*)

That is an important rule-of-law claim.

Arbitrary Power: Uncontrolled or Unruly

That the law should rule even over the most powerful people and institutions is a very old theme in the English legal tradition. The rule of law is commonly contrasted with *arbitrary* exercise of power; that, above all, is the evil that the rule of law is supposed to curb. This leads to another difference, this time masked rather than revealed by semantics. For arbitrariness is itself an ambiguous concept. Is it, for example, 'uncontrolled interference' or 'interference that is not subject to established rules' (Pettit, 2012: p. 58)? These are two of several (see Richardson, 2002; Chapter 3) conceptions of the concept. They have particular relevance to law; the former commonly being referred to as 'government under law,' the latter as 'government *by* law.' If one had to choose, there are strong arguments to favor the former over the latter (see Pettit, 2012), but ideally one would encounter the first always, and in exercises of public power the second as well. Not everyone opposed to 'arbitrary power' has had both these senses in mind, however.

As we saw, the common law tradition, from at least the thirteenth century until well into the eighteenth, maintained that the king was subject to a law that he had not made, indeed

that made him king. For the king, for anyone, to ignore or override that law was to act arbitrarily (see Reid, 2004; Palombella, 2010). Liberties, and procedures to protect them such as habeas corpus and due process, were enshrined in that law, and encroachment on such liberties was barred, even to the monarch, by the law. That that law was often *not* expressed in clear, prospective, general rules (see Maitland, 1965; first edition 1908: p. 383), today regarded as the essence of the rule of law, was not to the point (Reid, 2004). Indeed, given the customary, dynamic, fluxful, and evolutionary character of the common law as theorized by its adepts, it was beside the point (see Postema, 1986; Chapter 1). The issue was that it was superior.

From the eighteenth century, however, law came to be viewed increasingly as the direct or indirect product of the political legislator, the 'sovereign,' and in English law there was, at least arguably until very recently as a result of EU membership, no legal superior to the sovereign legislator. The conception of the rule of law gradually became more preoccupied with the character of the rules that the sovereign enacted: they should be clear, prospective, consistent, etc.

Shocked by this downgrading of the notion of a law superior to the sovereign, and by what they regarded as their own 'arbitrary' treatment by the British sovereign Parliament (Reid, 2004), the American colonists first staged a revolution, and then a pathbreaking innovation: a written constitution binding on the legislator, and in due course routinely overseen by an independent Supreme Court, whose decisions also came to be seen as binding on the legislator. This was a novel way of vindicating a very old principle. In England, old conceptions persevered, but in increasing tension with the legislative bias of modernity.

On the Continent, things were different. A *Rechtsstaat* was not just any sort of state, as we have seen, but one which operated on the basis of legal rules configured in particular ways. "[S]ituated at the heart of the theory of the *Rechtsstaat* is the question of the arbitrariness of power, of the potential violence inscribed in all relations of domination, whether private or public" (Heuschling, 2002: p. 42). However, partisans of the *Rechtsstaat* did not envisage a law superior to the state, a basis for appeal to some higher notion or other source of law. Law was a characteristic of the *Rechtsstaat*, but it was also its product. The nonarbitrary *rechtlich* quality of the state was a matter of the degree to which its edicts took the form of general rules that conformed to specific formal criteria and were supposed, in particular, to guarantee certainty and predictability. In this understanding, "[t]he *Rechtsstaat* means that the law is the structure of the State, not an external limitation to it. … Liberty is a consequence not truly a premise of the law. The authority vested in this conservative aristocratic state protected civil liberties as a service offered through the State" (Palombella, 2010: pp. 11–12).

The notion that state agencies must comply with a law above the State, only came with the development of written and legally binding constitutions, particularly in reaction to the Nazi calamity in the middle of the last century. Until then, although "it was in the state's interest to promote its self-limitation through self-binding to legal norms" (Loughlin, 2010: p. 320), and the people's interest too, it was up to the state to bind itself (*Selbstbeschränkung*). The common law tradition frequently, and in the seventeenth century vociferously, conceived of individual rights as protected by the courts *against* the Crown, whereas no such opposition existed in the German conception of the *Rechtsstaat* (see Rosenfeld, 2001: p. 1319), which, as Leondard Krieger shows, projected "older national assumptions which made the idea of liberty not the polar antithesis but the historical associate of princely authority" (Krieger, 1957: p. 5). The contrast is deep. As Gozzi observes:

> In Germany … the doctrine of the *Rechtsstaat* precludes the possibility of the primacy of law over the state. Indeed, it is precisely in the relationship between law and state – which in the German case is settled with the primacy of the state – that the most significant feature of the doctrine of the German *Rechtsstaat* emerges. Conversely, the English doctrine of the government of law is most clearly distinguished by grounding the rule of law on the superiority of law as proclaimed by the courts of justice. (Gozzi, 2007: p. 238)

From the point of view of those subject to the exercise of power, both its control and its manner of exercise, government under and by law, are important. But they are not the same. A state could be controlled but act under decrees with quite particular targets, kept secret from citizens, or inconsistent with each other, or retrospective, or without any decrees, let alone laws, at all. It could, conversely, be uncontrolled but act through promulgated, clear, consistent etc. laws. In either case, something significant would be lacking. For where arbitrariness in either of these senses is linked with significant power, it at the very least raises the reasonable apprehension that it will tend to: threaten the *liberty* of anyone subject to it; generate reasonable and enduring *fear* among them; and deprive citizens of sources of reliable sources of expectations of, and *coordination* with, each other and with the state. And as Lon Fuller (1969) and Jeremy Waldron (2011a) have emphasized, it threatens the *dignity* of all who find themselves mere objects of power exercisable at the whim or caprice of another.

These are four good reasons to value reduction of the possibility of arbitrary exercise of power (see Krygier, 2011: pp. 79–81). There may well be many others, such as those that commend themselves to many economists, having to do with the alleged contribution of the rule of law to economic development (Dam, 2006). To the extent that the rule of law can help deliver such reductions, this is reason to value it. This is not, of course, merely a negative matter of removing evils, but can be expressed positively. A society in which law contributes to securing freedom, confidence, coordination and dignity, is some great and positive distance from many available alternatives. There are other things we want from law, and many more things we might want in a good society, but ways of serving these values are goods immeasurably harder to attain without institutionalizing constraints on arbitrariness, in both these senses, in the exercise of power.

For some thinkers, speculating in these ways about what good might flow from reducing arbitrariness in the exercise of power, what it might be *for*, takes us beyond the analytical task of understanding what the rule of law *is*; for others it does not get us close to what matters. The former favor 'thin' accounts;

the latter lard their accounts of the rule of law with more ingredients and of different kinds. These are often known in the literature as 'thick' accounts of the rule of law.

Thin or Thick

Apart from questions of control versus character of law, writers on the rule of law often distinguish between 'thin' or 'formal,' on the one hand, and 'thick,' 'substantive,' or 'material' conceptions of it, on the other. The former limit themselves to formal properties of laws and legal institutions, which are purported to constitute the rule of law. The latter require substantive elements from a larger vision of a good society and polity – democratic, free-market, human rights respecting, or some such – to be present.

The first track is favored by modern analytical jurists. They have often adopted (Hart, 1967: pp. 273–274) or extended (Raz, 1979; Walker, 1988) Lon Fuller's eight principles of what he called 'the morality of law' as defining characteristics of the rule of law, even when they disagreed with him over whether they deserved to be called moral principles. According to Fuller (1969), these characteristics were that there must be rules, these rules must be publicly available, prospective, understandable, consistent, possible to perform, sufficiently stable for citizens to orient their actions by them, and administered in ways congruent with their terms. There is controversy over whether there is any reliable connection between such thin principles and substantive values beyond them (see Krygier, 2010: pp. 114–120) but whatever the view on that, on a thin conception those further values are something other than the rule of law.

Again, the *Rechtsstaat* has oscillated between thick and thin through its 200 years of evolution. It was first theorized by German liberal constitutional and administrative theorists, prominent among them Karl Rotteck, Karl Theodor Welcker and Robert von Mohl, seeking to characterize a legal order in terms of values it served (those values in their turn to be realized *in* and not *against* the state). The post-Nazi *Rechtsstaat* returned to, and richly amplified, a normative characterization based on the fundamental value, inscribed in the first article of the German Basic Law of 1949, of human dignity. However, in between times, after the failure of the 1848 revolutions and particularly under and after Bismarck, its late nineteenth-century and early twentieth-century versions were pared of normative adhesions, and strictly devoted to elaborating the formal components of a legal order that might properly be called a *Rechtsstaat*.

Not only legal philosophers, but also legal comparativists (see Peerenboom, 2004) tend to favor 'thin' versions of the concept, what might be called rule-of-law-lite: easier to identify and able to travel further, because it carries less baggage. Many governments, too, particularly authoritarian ones, prefer to be assessed against thin formal criteria, easier to satisfy than thick morally demanding ones. Today international businessmen, unwilling to buy into controversial questions about democracy, human rights and other large values in, say, Singapore and China (with both of which they might want to do business), often prefer a formal, thin, conception too.

Many, however, find thin conceptions quite inadequate. Ronald Dworkin, for example, was skeptical of conventional 'rule book' conceptions of the rule of law, which insist that "so far as is possible, the power of the state should never be exercised against individual citizens except in accordance with rules explicitly set out in a public rule book available to all. ... Those who have this conception of the rule of law do care about the content of the rules in the rule book, but they say that this is a matter of substantive justice, and that substantive justice is an independent ideal, in no sense part of the ideal of the rule of law" (Dworkin, 1985: p. 11). He, by contrast, regarded the rule of law as incorporating an ideal and an eminently positive and substantive one, "the ideal of the rule by an accurate public conception of individual rights" (Dworkin, 1985: pp. 11–12).

The sociologist Philip Selznick had a more complex combination of thin and thick. He agreed with those political realists who stressed the importance of strict legality as a restraint on, and saw the rule of law as a precious protection against abuse of, power (Selznick, 1992: p. 174). On the other hand, he insisted that there was a 'larger promise of the rule of law,' and this "thicker, more positive vision speaks to more than abuse of power. It responds to values that can be *realized*, not merely protected, within a legal process. These include respect for the dignity, integrity, and moral equality of persons and groups. Thus understood, the rule of law enlarges horizons even as it conveys a message of restraint" (Selznick, 1999: p. 26).

In Germany, the circumstances that moved prevailing conceptions of the *Rechtsstaat* from thin to thick were more dramatic than those that preoccupied Dworkin and Selznick. Indeed they were tragic. Already in the Weimar Republic, Hermann Heller rejected the legal positivist, formalistic, conception of the *Rechtsstaat* as crystallized by his contemporary, Hans Kelsen, which could accommodate any state. He argued for one that insisted that only a democratic state that depended upon and then institutionalized fundamental ethical principles was a *Rechtsstaat* (for the debates between Carl Schmitt, Hans Kelsen and Hermann Heller, which centered on the nature of the *Rechtsstaat*, see Dyzenhaus, 1997). Although Heller died in 1933, he already saw fascism as the great threat to such a state. His nightmare became real in the ensuing years.

In the perspective of German post-Nazi retrospection and introspection, thin conceptions came to seem not merely inadequate, but on their own positively dangerous. The *Rechtsstaat* embodied in post-war German jurisprudence thus embodies a strong commitment to fundamental rights and to the dignitarian premise of its 1949 *Grundgesetz* or Basic Law (see Grote, 1999), grounded in its unamendable Article I. This proclaims that "Human dignity shall be inviolable. To respect and protect it shall be the duty of all state authority." Particularly through the interpretations of the Federal Constitutional Court, this has spawned a rich jurisprudence of fundamental rights that characterizes the modern German understanding of the *Rechtsstaat*, or as it is frequently expanded (and at times complicated) to join the social welfare state (*Sozialstaat*), the *sozialer Rechtsstaat*.

There are problems at the extremes. What is gained by defining down a concept that bears so much normative

resonance, in terms that ignore any interrogation of what its point might be, and simply focus on the characteristics of institutions and practices? Particularly when it is not clear whether the characteristics chosen by 'thin' theorists relate as much to what law does and should do in the world, as they do to lawyers' unevenly informed intuitions and guesses about these matters. Again, what of the exercise of power by extralegal forces, social networks? If they are free to act arbitrarily, capriciously, whatever the law says, does it make sense to insist that nevertheless the rule of law exists because certain formal elements of a legal order are present? Excessively thin conceptions often seem urgently in need of a feed.

Yet, conversely, accounts that purport to be thin as a rake are often rather plumper than intended, particularly where – as is frequently the case in well-intentioned first world interventions in benighted countries – they embody parochial suggestions as to what features of familiar legal orders generate rule-of-law friendly results. When packages of legal *bric-à-brac* are asked to travel, it often turns out that they work very differently or not at all where they land (see Krygier, 2011). It might also turn out that institutions and practices of sorts not known in the homes of confident rule of law exporters perform adequately in their own homes, even if they look quite strange to visitors. Whether they do or not should be a matter of investigation, not overbearing legalistic assumption. Too often, however, imported assumptions about the working of legal institutions, based on distant histories, traditions, institutions, and practices, have been smuggled in and then re-sold as though of universal applicability. When they fail to 'take' is it because the rule of law is a false ideal, or because what has been exported is not the rule of law itself but parochial institutions taken to be necessary for values that might yet be reached, and need to be reached, in other ways?

Partisans of thin versions, on the other hand, often associate the thickness insisted on by moralists with a combination of parochialism and imperialism about values and institutions. Why should we assume, either as a matter of fact or of value, that all cultures value the same things from law? Metaethical disputes this raises are too large to be resolved here, but there is another worry about too thick an account of the rule of law. As Joseph Raz has argued, 'thick' conceptions have a tendency to wash away all distinction between the rule of law and anything else we might want. That lays them open to the criticism that "[i]f the rule of law is the rule of the good law then to explain its nature is to propound a complete social philosophy. But if so the term lacks any useful function. We have no need to be converted to the rule of law just in order to discover that to believe in it is to believe that good should triumph" (Raz, 1979: p. 211).

Such criticism points up another inadequacy of the choice on offer: the dichotomy between a spare and formalistic thinness, on the one hand, and a pudgy confection of everything we would like to find in a good society, does not exhaust the field. There is space for values particularly associated with the exercise of power, what might be called distinctively *legal* values were it not for the fact that the differences between them and other values are unlikely to be categorical, but rather matters of focus, shades, and degree. Many legal orders bear and transmit long histories of observation, experience, and reflection upon the pathologies of unconstrained and/or capricious exercise of power and on what might be done to avoid or moderate such pathologies. Legal orders typically embody and generate values related to what they do, both in their animating principles and ideals, and in the complaints they provoke when their practices flout the sources of their legitimacy (see Selznick, 1999; Waldron, 2011a). These have included such values as due process or natural justice, ideals of fair treatment and notice, and in particular legal traditions much more. They have to do with treating a subject of power with the respect due to a person, rather than a 'rabid animal or a dilapidated house' (Waldron, 2011a: p. 16). The rule of law might well be argued to be incomplete to the extent that some such power-related values, that have to do with how to arrange and transact potentially harmful interactions between it and its subjects (too often treated as objects), are dishonored. Attempts to vindicate such values, often implicit in many legal principles and traditions if not all legal rules, might be considered a service to the rule of law, even if they go beyond purely formal aspects of laws and notwithstanding that they might fall short of justice more holistically conceived. On one view, the special disease, to which the rule of law is part of a remedy, is the propensity of power unconstrained to be exercised in arbitrary ways. It is a widespread disease.

Anatomy or Teleology

More fundamental than contests over the fleshiness of the rule of law is one over whether we should begin with focus on its anatomy, the institutional features one should expect to find in such a creature – or its point – the reasons one is concerned with this rather than something else. The long common law tradition was not fixated on specific institutions, even less the precise character of legal rules. As Reid demonstrates, it was all too murky: "Ironically, the medieval constitutional law out of which today's rule of law developed would not have met the requirements of clarity or precision. There was always an air of indefiniteness, a smoky vagueness surrounding this all-embracing restraining 'law' of English constitutionalism. Even its authority as law was shrouded in immeasurability" (Reid, 2004: p. 16). But the common law tradition was clear on one thing: "It was, Viscount Bolinbroke said in the eighteenth century, a matter of curbing power and not of the type and structure of government. Whether power was vested in a single monarch, in 'the principle Persons of the Community, or in the whole Body of the People' was immaterial. What mattered was whether power was without control. 'Such Governments are Governments of *arbitrary Will*,' he contended" (Reid, 2004: p. 42). Bolinbroke would likely be puzzled by the rule of law toolkits carried by UN and World Bank rule of law promoters throughout the world today; uniform in character, diverse in application, apparently universal in application. Why are *those* particular institutions sacrosanct? What is the *point*? How has the point influenced the kit? Even for those of us who have left the mythologies and hagiographies of common law theory long behind, these are not bad questions.

Similar choices are also found in the *Rechtsstaat* tradition. The early propagators of the concept were not legal anatomists but proto-liberals in the main, many influenced by Kant, seeking to establish an order of citizens equal before the law, whose personal autonomy and property were protected by the law. A state was a *Rechtsstaat* to the extent that it achieved these tasks, not because it had this or that particular form. As von Mohl put it, "the objective of the *Rechtsstaat* is not logically entwined with a particular form of government; on the contrary, every arrangement of public power which guarantees the right and the development of all human activities, is admissible" (quoted in Heuschling, 2002: p. 59; my translation from Heuschling's French). These writers were explicit that what mattered was achieving what they conceived to be the point of the rule of law, not whether it exemplified a particular form of institutional architecture. That understanding did not continue through the nineteenth century, but was supplanted by a formalistic, anatomizing conception, stressing the positivistically characterized features of a state, that qualified it to be declared a *Rechtsstaat*.

On the teleological account, however, the rule of law cannot adequately be explicated by a list of features of legal institutions, rules or practices. For the rule of law occurs when and to the extent that there is a social *achievement* to which law contributes. If we say, for example, that there were lots of laws under Stalin and a lot of rule, but there was not much rule of law, we are not saying something controversial, and you would not have to know much about Dicey or Fuller to agree. So at least among the legally and philosophically unwashed, the rule of law has something to do with what the law does, rather than simply with what it has been somewhere declared to be.

Moreover, if the law is enlisted to do things we associate with the rule of law but the mission fails, we might say that there was an attempt to achieve the rule of law, but it was unsuccessful: laws were of the sorts we associate with the rule of law, everyone was trying, but they were overborne, for whatever reason. To say the rule of law exists in a society is to imply an accomplishment; among its partisans a valued accomplishment: an ideal to which law is taken to contribute has been approached.

On this view, the rule of law is not a natural entity like a tree, simply awaiting scientific description, or even a man-made contrivance like *a* rule of law in a statute book, which might be identified by pointing to it. It exists to the extent that a certain state of affairs, one in which power is exercised in relatively nonarbitrary ways, exists in the world. Law is supposed to contribute, though it will never do so on its own. The aspiration or ideal is satisfied only *insofar as* some purpose or goal for law is realized. While such an achievement could in principle be thought value neutral or even valueless, and has been, the rule of law also has partisans – today perhaps, even too many – who think it valuable, an ideal for law. If we value that ideal we should of course seek to identify what might be necessary to generate it. But that is a second step. Without some principle of selection even if only tacit, we won't find a bunch of legal bits and pieces waiting 'out there' and recognizable as the rule of law.

The teleological contention is, then, that to understand what the rule of law requires we need to start by reflecting first on its *point* rather than, as is more common, with an enumeration of purportedly defining legal-institutional *features*, whether they be particular institutions such as common law courts (Dicey, 1961), particular formal qualities of rules, such as prospectivity, clarity, etc., or even traditions and procedures, such as defences, *habeas corpus*, and so on (Waldron, 2011a), though the last is getting closer to explicit concern with the specific point of the rule of law.

At first blush, this looks like a repetition of the distinction between thin and thick, and it is true that anatomical accounts of the rule of law are often 'thin,' since they focus on delineating the characters of legal institutions. But there are two differences. First, particularly among rule of law promoters, it is rare that anyone has thin ambitions, more commonly they just have confused ideas of what the rule of law is about. Rule of law promotion, after all, is ostensibly an attempt to enlist the rule of law to do good in the world, not just to build replicas of institutions from home. However, rule of law promoters are often restricted by the conventional identification of the rule of law, or *Rechtsstaat*, with a particular box of tricks, and proceed to try to vindicate some purpose with an a priori catalog of what is needed to achieve it, rather than an openness to the possibility that they might need to learn some new tricks. Awareness that one should start with the end, as it were, rather than purported means, might avoid a lot of grief over transplants that fail to do what is expected of them: promote the rule of law.

Moreover, the distinctions between thin versus thick, on the one hand, and anatomical versus teleological, on the other, do not occupy the same plane. A teleological account is not necessarily normatively thick; it might occupy itself with a small point, say predictability in the legal environment. How normatively enriched the point of the rule of law might be is a legitimate matter of debate, but it is a debate on the teleological plane. On that plane, the question is not, first of all, how much normative weight the concept carries but where one should start to think about the rule of law – by enumerating a set of purported (and typically universal) features or by asking what it is might be good for. Since it is hard to know what features matter unless one has sorted out what they are for, the suggestion here is to start with the end.

Legal or Socio-legal

If one is concerned with underlying values that inspire commitment to the rule of law, this has significant and somewhat paradoxical implications for where one should look to vindicate whatever one decides such values to be. For the search to redeem them is likely to decenter law itself. After all, it is in principle an open, and likely variable, matter what in the world best minimizes arbitrariness in the exercise of power, and the same might be said of any other values that we imagine law helps vindicate. Yet if ends matter, then it is not clear that one should *assume* that law is always key to achievement of the animating values of the rule of law, even less the state. This is so, whatever the values one has in mind, and it will be all the more so as one ramps up the values one associates with the rule of law. A good society is quite an achievement, and law only a small, if precious, contributor.

This applies at virtually every level. If arbitrary power is to be feared, then wherever power is powerful enough to be fearful, rule of law concerns are relevant. Thus, preoccupation with the state is not always appropriate, in circumstances where many of the sources of restraint on arbitrary power, many dangers flowing from it, and many of the goods accomplished by its curtailment, lie outside the state, and many of the means of achieving those goods lie outside the law as well (see Krygier, 2011: pp. 85–91).

If that is the case, it is not obvious that the familiar institutions associated by legal anatomists with the rule of law will always be the best to wield. Law will never accomplish much in the world on its own, and a key accompaniment of investigation of the rule of law should be, but rarely has been, study of what else is needed, beside and beyond, law, to attain its ends.

On this view, law should be viewed, not as the always-necessary centerpiece of power-taming policy to which other measures are subordinate or supplementary addenda, but as one implement among several, of varying significance, in some respects and circumstances of potentially unique importance, but dependent for its success on many other things, and perhaps not more important for the achievement of its own goal than they. Similar reflections apply, but all the more, to the State of the *Rechtsstaat*.

There is something to be said for the legal pluralism embodied in the old common law tradition, and squeezed out by the rise of the contemporary state: in principle in the *Rechtsstaat*, and by the statophilic tendencies of modernity more generally. Even with its dominance, and especially where it is 'failed,' 'fragile,' or 'transitional,' the state is never the only game in town. That is a sociological platitude, but it should have more bearing on legal platitudes than it has. Lawyers will naturally, habitually, focus their attention on state and legal agencies, but those interested in promoting the values that underpin the rule of law and make it worthwhile will need to look further afield.

If the foregoing considerations are plausible *within* existing nation states, they must be all the more compelling for anyone who wants, as many today do, to speak about an emerging 'international rule of law' (Palombella, 2009; Waldron, 2011b). For whatever that might mean, there is no international *Staat* to be its lawgiving and enforcing source. It might be a matter of argument whether it is a good idea to seek to extend the rule of law to the international sphere, but it would seem a strange truncation of the argument simply to rule out a nonstate-centered rule of law by *definition*.

This suggests the need for a sociological awareness and sensibility not especially common among lawyers, whether rule-of-lawyers, or *rechtsstaatlich* ones. There will be other sectors of a society altogether that influence the extent to which the values at the heart of the rule of law will be attained. Paradoxically, in order to reach those values we will have to look far beyond the institutions we have most conventionally associated with them.

That does not make either the law or the state unimportant. However, it might enable us to see their importance in perspective, give due weight to other phenomena that might need enlisting to serve such goals, and release us from the hold of a mantra, whether 'rule of law' or *Rechtsstaat*, which in their modish ubiquity threaten to obscure the valuable, indeed precious purposes for which they were pushed into the fray, instead promiscuously to serve virtually any purpose you want to name.

Rumors and Urban Legends

Abstract

Rumors are claims about events or situations that are passed primarily outside official channels and are not based upon substantiated facts. Urban legends are a subgenre of rumor with a more complete narrative. Rumor research in social science is limited and sporadic, yet plays a vital role in understanding beliefs, attitudes, emotional states, and worldviews that cannot, or will not, be openly articulated. Both social and technological shifts have influenced the analysis of rumor and urban legends.

Introduction

Rumors are claims about reality – particularly events, people, and situations – that are circulated primarily outside official sources of knowledge, such as mass media sources, organizational authorities, or government agencies. There is nothing in this definition, widely agreed upon in rumor studies, which requires a rumor to be false. It is hard not to associate it with falsehood, since false rumors fascinate and frustrate us, and in some cases, they pose grave dangers. Nonetheless, rumor is marked by its process and not the truth or falsity of its content.

Indeed, the troublesome image of rumor that we have inherited stems from its capacity for wreaking havoc – whether the rumor is false or true. Social and behavioral scientists have had a tendency to drift toward this 'havoc' view, despite sporadically acknowledging that rumor is an integral part of social life, and that often it is a side-effect of conflict rather than its instigator. Dramatic events are associated with it, we fear its power, and yet our disciplines have had difficulty over the years in sustaining interest in the topic. New scholarship on the subject is often spawned by necessity as a real world set of problems emerges, followed by years of relative inactivity in published research. As such, many social scientists interested in the topic have relied on the work of humanities scholars, as well, especially the interdisciplinary field of folklore. In this field, rumor is regarded as a timeless genre, and as such continuities across history and cultures have been emphasized. Folklore has been particularly good about cross-cultural research, the historical lineage of particular rumors, and symbolism. Social science approaches, in contrast, demonstrate strength in relating rumors to social consensus and conflict, to the role of rumor in crisis situations, and to its relationship to psychological states, cognition, and psychodynamics. Social psychology has demonstrated more consistent effort in rumor studies than other social science fields.

Historically, rumor has been spread by informal speech between individuals, either serially one to another, or in groups. Occasionally, both rumors and urban legends have been transmitted with handbills or flyers. Recently, of course, a significant conduit has been the Internet, including e-mail, webpages, and social networking. *Urban legends* are a subgenre of rumor. They typically stand alone as full narratives whereas rumors are claims, which are only sometimes linked together. Urban legends typically have greater longevity than rumors, can change their details rapidly to recontextualize their content to time and place, and resist debunking because elements of their claims are often flexible. Urban legends are sometimes called contemporary legends by researchers, reflecting the fact that these tales are often not 'urban' in the sense of being tied to city life, but rather that they have strong themes of danger and redemption specific to modernity and mass society, in contrast to small-scale societies and the folklore generated in those contexts.

Why is social science input on rumor and urban legend important? First, rumor can have social impacts that may be subtle or bold, dire, or trivial. It can accompany collective violence (though it is often not clear whether rumor incites it, or is used by aggressors as post hoc justification for it). It is sometimes genuinely hard to tell how responsible rumor is for an outcome involving it. In some cases, we may be able to effectively intervene if a rumor is leading to destructive behavior, harmful misperceptions, or individual or collective stress. As Knapp (1944) noted in his landmark article on the psychology of rumor, rumor studies enable the study of social attitudes, beliefs, and opinions in a way that circumvents social desirability bias. Since respondents do not claim to be the authors of a rumor, we can find the tacit beliefs, fears, wishes, and attitudes 'underneath' public opinion. The implications for social science are also general: the continued importance of learning to study things that are not easily measured, the integration of key insights from studies using different methodologies, and the clear need for cross-cultural and cross-disciplinary research.

The History and Heyday of Rumor Research

The birth of modern psychology in the nineteenth century brought the first experimental and psychoanalytic approaches to rumor. From the beginning, emerging tensions within psychology about the nature of group communication and behavior shaped the study of rumor. One experimental approach was designed around the general problem of hearsay, but applied to rumor more specifically. The analogy that experimenters appeared to be using was the children's game 'Whisper Down the Lane' or the parlor game 'Telephone,' where

a message changes meaning as it is passed from person to person. Distortion was primarily an informational problem, with a series of linear, cumulative chain errors appearing as the text was passed along (Hösch-Ernst, 1915; Gorphe, 1927). Of course, the researchers conceded that the new, distorted text had to be intelligible and plausible, but it was otherwise devoid of intentional creation or reshaping – rather, it was an ordinary consequence of communication. Although this somewhat mechanical view faced competition from the psychoanalytic model, and would later be supplanted in experiments by a more complex view of human communication, it did endorse an important element of rumor – the ordinariness of it. Rumor, once it exists, will travel, and it will be distorted, regardless of its content. Strangely, the ordinariness or inevitability of rumor has often been obscured in later work. Even so, the insights from these early studies were limited. Was rumor really like any text passed along from one person to another, or was it distinctive? In what way? Rumors are also sometimes true – how would their factual nature remain preserved if distortion was inevitable?

Early psychoanalytic approaches emphasized a different model of rumor, and some of these basic insights have stood the test of time. The key role of the unconscious emerges when we realize, as Von Roretz (1915: p. 28) suggested, that rumors purport to be claims about reality or news; neither opinion nor speculation, but real. As such, the teller avoids responsibility for what they are saying, and merely claims to be passing along information. The emotional investment in rumor, Prasad (1950) suggested, stems from the way in which it can provide justification for anxiety or fear, and reflect a desire for companionship in one's feelings. Many agree with the view of Rosnow and Fine (1976) that rumor plays a role in reducing anxiety – whether collective or individual – by repackaging information into more acceptable forms. The task of the researcher, in this case, is to identify not only the source of anxiety but how the repackaging fixes the problem or resolves confusion. If the anxiety-reducing factor is central to the continued appeal of rumors in a multimedia, multiplatform world of information, it is probably because rumors and urban legends offer the teller and hearer a creative role in shaping the claim while disavowing their very shaping of it.

During the heyday of rumor research in the United States, during World War II and directly after, social scientists attempted to formulate a working set of observations or 'laws' of rumor. This effort has been modestly successful in the sense that some distilled wisdom from wartime rumor research has stood the test of time and new venues. The unconscious hostile impulse, in their view, partially explained rumors, but researchers did not necessarily agree what weight to give it, nor did they agree how the problem could be most expertly managed, or whether critical-mindedness could prevent it. Caplow (1947) found that critical-mindedness did not necessarily stop a rumor; rather the rumor was more likely to be more *accurate* as it passed through skeptical ears. Critical-minded participants were more likely to look for verification, and this, rather than transmission per se, explained some sharpening of detail.

Another open question that stems from this era is just how strong a rumor-monger, or a belief in a rumor, needs to be in order for the rumor to take hold. Wartime rumor studies always considered the role of intentional subversive propaganda in fostering rumor, even finding instances of Axis radio messages that seemed related to the content of domestic rumors in Ally countries. Yet, by and large, rumor researchers have been more interested in how and why rumor intrigues the general public, rather than who started it. It is a broadly shared axiom among rumor scholars that without some key feeling of relevance to individuals or groups, a rumor will not be successful. Intentionality or malice in the spread of rumor continues to be emphasized in some communications and political science research (cf Sunstein, 2009). Most social scientists believe that the origins of rumors are often not singular or specifiable, and are often sincerely believed, even when clearly vicious, ridiculous, or destructive.

Knapp's work in a Massachusetts public safety agency led to his widely adopted typology of rumor (1944). There are *wedge-drivers*, *bogies*, and *pipe-dreams*. Wedge-drivers typically accuse a group within society of collective bad deeds against the interest of the whole. For instance, Knapp found war rumors, collected in September 1942 in the United States, that accused Catholics or Jews of evading the draft, or accused Ally countries of manipulating the war effort to American detriment. It is noteworthy in thinking about the distinctiveness of rumor that wedge-drivers were rarely directed at the Axis countries; this makes sense if we understand rumor to be a thing that cannot be easily voiced or endorsed – there was really no social risk in saying negative things about Germany, Japan, or Italy during the war, since that animosity was quite overt. Two-thirds of the rumors Knapp collected were wedge-drivers. Bogies, or fear-driven rumors, were the second most common, accounting for about one-quarter of the war rumors. The major theme for these rumors was that things were worse than they seemed, and these rumors were often graphic in their claims of hidden mass casualties (bodies washing ashore that were not reported; or the entire fleet at Pearl Harbor destroyed) or contamination of everyday products. Finally, a small number of war rumors were pipe-dreams or wishful thinking rumors, such as an early end to the war because of depleted Axis supplies. Knapp also speculated that the preponderance of different kinds of crisis rumor might shift as the crisis unfolded – perhaps more wishfulness in the beginning and more scapegoating, wedge-driving ones as the burdens of the crisis impinged on regular life. The preponderance of wedge-drivers during war is not necessarily universal: Nkpa's study (1975) of rumor during the Nigerian civil war, 1967–70, found many more pipe-dream rumors and lower levels of wedge-driving ones.

In all cases, war rumors generally presume that the truth is being at least obscured if not completely hidden from the public, and in some cases official secrecy makes this plausible. As such, Knapp was the first to propose a still widely endorsed view of rumor management: intensity of rumors varies inversely with the availability and trustworthiness of official information. The greater candor and clarity possible from government, civic, and media organizations, the easier it would be to quash or at least limit the appeal of rumor.

Common Denominators in Rumor Episodes

Allport and Postman (1947) first identified three characteristics of rumor as they travel. First, rumors are *leveled*: this is the

tendency of the rumor to become shorter and simpler. Second, they are *sharpened*: some details drop away and others are retained, and the total quantity of detail is reduced. Finally, the rumors are *assimilated*: new hearers, if motivated to reshare it, will make small changes, and sometimes big ones, that are consistent with their own interests and assumptions. Allport and Postman's experimental methodology reproduced the serial transmission model of the early psychology studies; many researchers have since questioned whether this is really a suitable analogy for the spread of rumor in real life (Buckner, 1965; Shibutani, 1966). Prasad (1935), who studied rumor and natural disaster in India, found relatively little distortion of rumor; the same rumor would emerge among different groups. Peterson and Gist (1951) found a great deal of *snowballing* or creative elaboration, rather than leveling or sharpening, in the circulation of rumors. Other researchers have found that rumors can invert their claims depending on their social location, for instance, when traveling across a racial or ethnic divide (Turner, 1993; Knopf, 1975). A rumor of an atrocity in a neighboring town can accuse a group of black assailants of attacking a white victim, and nearly simultaneously the same rumor will appear with a group of white assailants and a black victim. Certainly the common observation that rumors tend to beget other rumors complicates the matter a bit, even if the content of specific ones becomes simplified over time.

Assimilation, which has been perhaps the most agreed upon of Allport and Postman's three characteristics, also implies that a rumor's strength may be tied to how easily it can be adapted to an individual, group, or society's interests and assumptions. "Rumors are credible because they reference the worldviews of those that share them" (Fine and Turner, 2001). While Allport and Postman emphasized the individual's readiness to integrate rumor material into their worldview, subsequent researchers (Bordia and DiFonzo, 2002) emphasize the need to add cultural, social, and historical layers in order to understand the plausibility and appeal of a rumor. DiFonzo and Bordia's analysis of corporate rumors (2002) further suggests that levels of anxiety may explain much of what we think of as interest or importance. Assimilation helps us understand why rumor spread patterns look the way that they do; for instance, why one rumor might be a small sector rumor and another more widespread and traveling across more varied social territory.

The work of pioneering researchers during World War II was prompted by the desire to control rumors. Government agencies, mainstream media sources, and civic organizations seemed to agree that rumors about the war and its effects on the home front threatened subversion, in 'loose lips sink ships' form (Rosnow and Fine, 1976) or that rumors could erode morale, particularly ones that alleged that certain imposed hardships at home, like rationing, were either unnecessary or being evaded by elites. Allport and Lepkin's study (1945) of rationing rumors concludes that the primary factor in their promulgation was the lack of access to accurate information. About the research participants that represented the stressed public, they asserted that "the more information he has, and the more carefully he thinks, the less chance that he will be led into believing by his inner, and often unrecognized, impulses." The alternative, rejected hypothesis was that the privation of rationing itself generated enough stress to cause greater vulnerability to such rumors. This assumption set the stage for the 'fight claims with counter-claims' model of rumor intervention that would later prove less than effective, since it tended to sideline the emotional fuel of rumor despite its recognition of 'impulse.'

Allport and Postman identified *salience* and *ambiguity* as the key elements of rumor's vitality. By salience the authors meant that the topic must be of some importance to the group of people who hear it and perhaps retell it. Without this basic element, a mere word-of-mouth fiction would not be transmitted much, or it will only be transmitted in groups that find it salient. For instance, rumors in the 1980s about large corporations being fronts for satanic organizations were of little interest beyond people who were a part of conservative religious movements (Koenig, 1985). Nonetheless, the rumor enjoyed an intense period of transmission and belief within that subculture. Salience does not require fervent factual belief in a topic, or at least about its central claims. Victor (1993) describes a 1988 rumor panic in rural southwestern New York state, alleging ritual sacrifice and other kinds of satanic cult activity. The panic affected everyday life and cast suspicion on nonconformists. Its salience was not limited to religious conservatives, but extended to those who 'half-believed' the rumors enough to think that something must be going on that threatened the safety of their children – and that threat was enough to shape behavior. "A rumor persists," Victor notes, "when it offers a plausible explanation for people's shared anxieties." The region was suffering from a rapid postindustrial economic decline and an alarming rise in family strain indicators, such as divorce filings and child welfare caseloads. The anxiety around the future was real enough, and the primal need to protect children made the rumors salient even to those suspicious that it all might be nothing. Anxiety may be one sort of emotional engagement, which seems necessary to turn something merely relevant to one's situation into something salient enough to be worth believing or passing on. Rosnow argues that anxiety may well be intertwined with heightened perceptions of ambiguity as well as a motivational ingredient in salience (Rosnow, 1980).

By ambiguity, Allport and Postman meant that some larger situation, of which a rumor is a specific part or attempted explanation, is characterized by uncertainty or a lack of trusted information from a reliable source. This latter factor, ambiguity, is the reason why rumor seems to intensify during crisis situations. Reliable sources may be absent, or simply unable to communicate what is known or unknown about the crisis. Official sources might also be distrusted, either because the source has failed to be candid and forthcoming in the past, or because there is generalized distrust between the source and the public. A central assumption emerged that ambiguous situations create a vacuum, which rumor fills, and thus a reduction in ambiguity will reduce rumor intensity. Yet this is easier said than done, since in some cases ambiguity is not objective, but asserted and elaborated by rumor hearers and tellers themselves (Donovan, 2007).

The anthropologist Raymond Firth (2011) found that among the Tikopia of the Solomon Islands in the early twentieth century – as is certainly the case for many parts of the world still today – the distinction between 'news' and 'talk' was a bit artificial. "The news is received as conveyed by individuals, but often treated as if it stemmed from a generic social source."

Yet this did not preclude scrutiny and doubt, and when a rumor proved false, children were often blamed. Firth notes that the Tikopia often suspended judgment of the truthfulness of accounts until a later date, and passed it on conditionally – but nonetheless continually.

Modern Mediated Societies and Rumor

In Western industrialized societies, there is an expectation that because continuous and accessible government, civic, and media sources are available, they will be utilized by members of society to clarify what is true and what is not, or at least what is verified versus what has been just heard by word of mouth. Research like Firth's should give us pause about this expectation – does it even uniformly apply, or describe people's real world behavior, in a media-saturated environment like our own? Ralph Turner's study in the 1980s of earthquake rumors in the Western United States suggested that increased scientific and official communication did not quell rumor – it simply shifted its focus. About half of the people in Turner's study believed that authorities were withholding something; demand for information increased alongside increased official communication. In contrast to Allport and Postman's model, Turner suggests (1994) that "the reduction of ambiguity forces people to pay attention to unpalatable news and instigates intensified individual and collective information seeking." The official reduction of ambiguity, in essence, can backfire as it enhances overall salience, and thus spawn even more speculative rumor. More recently, the work of Weeks and Southwell (2010) seems to confirm this problem. Using Google Trends to track its search engine activity related to the rumor that US President Obama is a 'secret Muslim' the researchers find evidence that media reports about the rumor – even when, as in most cases, the reports debunk the rumor – decisively influence Google searches the next day. Online searches then lead the curious into more speculative and unsubstantiated territory.

A further problem emerges when authorities themselves promulgate rumors, and these are treated respectfully by the media. Consider tales of kidney theft, which circulate worldwide. Even those given to skepticism about domestic kidney theft (the businessman on holiday who loses his kidney in Vegas) will give more credence to the idea, once the environs shift to the peripheries of Eastern Europe, Asia, or South America, and when the victim shifts to poor or homeless children. In her book *Organ Theft Legends*, Campion-Vincent (2005) shows the relative success of this version of the tale, weaving together local rumor, news accounts, and unsupported claims by politicians and activists, and providing a global chronology. This approach avoids the common mistake of overlocalizing the meaning of rumors based on a current, site-specific set of strains, and often well-earned suspicions. An imagined black market in stolen organs would have to overcome formidable technological and social barriers, but would also be heavily dependent on impeccable, permanent silence of the highly skilled thieves and brokers. Opinion leaders were found in Campion-Vincent's study to repeat each others' claims and long-debunked allegations 'as if they had never been denied' even though they were all in a position to help dispel rather than encourage the rumors. Campion-Vincent shows that not only do organ theft rumors occasionally become pretexts for mob violence, but that trust between doctors and poor patients, and between the government and citizens is eroded. Of course, corrupt, brutal, and neglectful governments may help foment the conditions that cause belief in such rumors in the first place, but the recognition that such rumors also flourish in developed countries should give pause to those who make a simplistic equation between structural exploitation and the plausibility of rumors.

Allport and Postman's model treated ambiguity as an objective characteristic of the circumstances in question, though the authors acknowledge that individuals could subjectively find it were it not there. For wartime researchers and those that have followed, it is a matter of emphasis. Knopf, who wrote about race, rumor, and riots in the 1960s, asks whether ambiguity really stands alone as a measurable variable. In her account, the underlying conflict shapes what is known and unknown. "Take away the adversative aspects of an event and you take away much of its ambiguity" (Knopf, 1975). Thus while the ongoing rumor process may be built upon ambiguity, this ambiguity in turn is inherently built upon existing conflict. People decide how clear things already are – or are not.

Shibutani also studied rumor during wartime, but from a quite different angle. Though his landmark book *Improvised News* (1966) incorporated previous work on World War II rumors, the heart of the study was his own on-the-scene account of rumor among Japanese-Americans in internment camps in California. It was methodologically distinct, and inspired others later to look at rumor in social context, rather than only through experimental methods. Shibutani's major thesis was that rumor was a normal and not a pathological part of social life. He saw it as a problem-solving activity by groups of people who were deprived of enough trustworthy information. Shibutani's work also shifted focus away from individual tendencies toward gullibility or rumor mongering to a model where people with a variety of critical abilities and social intentions participated in the shaping of rumor. *Improvised News* inaugurated an era of careful, qualitative, situated studies – about rumors concerning everything from kidnapping and sex slavery in Orleans, France (Morin, 1970), to the covered-up 'death' of Beatle Paul McCartney (Suczek, 1972; Rosnow and Fine, 1976). Followers in this method, though, later wondered whether Shibutani had overemphasized the cognitive and rational needs of internees for clarity and closure. Was information seeking their only motive for collective rumor building? What about the respondents in many on-the-ground studies who have no desire to seek clarification, confirmation, or the ultimate truth-status of a rumor? Goode and Ben-Yehuda (1994) argue instead that "the last thing people who tell rumors want is verified information."

Despite a decline in interest in the topic of rumor after the late 1960s, a handful of significant empirical and theoretical challenges emerge from scattered studies. Folklorists began to take more interest in contemporary rumor in the 1970s and in English-language journals, interest shifts to the 'urban legend.' Jan Harold Brunvand has collected urban legends for longer than 30 years and has published several popular-audience books, with an emphasis on those legends circulating in the United States. Tying a number of widely believed tall tales together, Brunvand (1984) senses subterranean regret about

the loss of small-world charm and social familiarity; a strong undercurrent of general suspicion of others animates these types of rumor, as opposed to the specific suspicions of more provincial times.

Urban legends, as a subgenre, underscore the often idle nature of rumor. Not all negative, accusatory rumor results in overt conflict or violence. Sometimes, there is a simple meeting of minds over rumor where the interlocutors commiserate that 'that's how it is nowadays.' Though they may be destructive in the long run, they often shore up short-term solidarity and a feeling of apprehending the same greater reality as others through the symbolism of the claim or tale. Little action is provoked. Miller's study (1992) 'Snakes in the Greens' examines the emergence of this already-circulated-elsewhere urban legend in a low-income, mostly African-American neighborhood, alleging that an elderly woman was bitten by a snake in a grocery store's produce section, hiding in bunches of greens. Miller shows how the rumor was used – as opposed to being believed or disbelieved, per se – among neighbors in casual conversation. It illustrated how little regard this corporate-owned grocery store had for its patrons, who did not have many options in choosing a place to buy food. Many who heard or shared the tale knew the rumor was 'silly' and likely a tall tale, but it provided a common object to foster a larger discussion of corporate malfeasance and community neglect. There was no desire for official confirmation (or denial), nor any call for a boycott.

Patricia Turner's study (1993) of modern rumor in African-American culture examines how racial oppression and conflict throughout American history have been accompanied by rumor cycles among both blacks and whites, alleging planned and emerging group violence. But consumer legends also are customized to community themes. The rumor that a soda brand popular in minority areas causes sterility in black men, or ones that allege Ku Klux Klan ownership of certain fast-food franchises or expensive sneakers, act as conduits of more long-standing alienation.

Another question about rumor as a whole is raised in these examples: Are rumors generally negative in content? While there is no central database of rumor worldwide that would allow a definitive answer to this question, it does appear that most rumors and legends have a negative core. French researchers are comfortable suggesting that the ratio is likely 9-to-1 in favor of the negative (Renard, 2005). Rumors tend to warn of such things as a new, incipient threat or a secret reality that we have been hoodwinked about. Even positive rumors such as consumer reward rumors, where a rumor suggests that a certain behavior (saving soda can lids, forwarding a certain number of e-mails) will result in the consumer or a charity being rewarded, have a subtle element of negativity to them: either the implication that the finance of ordinary activities is dependent on these sporadic and minor contributions, or that the wealthier entity is 'holding out on' or exploiting the ordinary consumer and the rumor cleverly exposes the secret. There is nothing superficially negative about a chocolate chip cookie recipe that has been shared informally for the last 20 years – but it is wrapped in an interesting rumor. A certain premier department store, it has been said, was serving the cookies and offering to sell its customers the recipe. Assuming the cost would be nominal, the shoppers agreed, only to find on their charge card statements that they had been billed $200 or more for the recipe. The rumor, which unleashed the recipe for free, purported to be a consumer's revenge. The store denied that it had ever served the cookies or sold any sort of proprietary recipe. Everyone agreed that the recipe makes a rather delicious cookie, so it is still interesting that a negative story comes with it (Brunvand, 2012).

Conversely, even some very negative rumors and urban legends contain positive elements, usually intertwined with the act of dissemination itself. In the actual performance of warning rumors and legends, the promulgating of the rumor itself claims to be an act of protection toward others. In Donovan's study of crime legends (2004) the promulgation of the rumor is tied to the desire to keep others safe, even though safety information could simply be hoarded for a personal gain in perceived safety, or a sense of superiority over more foolhardy nonbelievers. This helping stance is apparent both from the text and the talk around the text that went on in online forums. Incompetent criminals and others engaged in antisocial behavior are quite often getting their comeuppance in urban legends, such as the robber identified by a unique injury obtained during a crime in 'The Choking Doberman' (Brunvand, 1984).

Heath et al.'s (2001) study of the content of contemporary urban legends found that there was a significant bias toward the 'disgusting' as a common element of urban legends. They also suggest, from their experimental-method studies of reactions to urban legends, that they can inflict, rather than just reflect, things like disgust, which are broadly shared 'across individuals.' This quality essentially circumvents critical evaluation. Koenig (1985) noted about fast-food contamination rumors that, "Just the thought in the back of one's mind of worms in hamburgers was enough to steer one to the pizza parlor." The fast-food hamburger joint could suffer in sales, even if hearers of the rumor scoffed at its likelihood. These insights may explain the staying power of some everyday rumors – ones that are not particularly bound to crisis or conflict situations, at least not overtly.

So far we have assumed a stability of elements of rumor telling, even if we struggle to characterize it. But are rumor behavior and our relationship to information the same in a society over time? Even before the rise of the Internet, Klapp (1972) suggested that rumor serves each historical circumstance differently. One of the modern appeals of rumor may be offering an overmediated but less trusting society with more raw material for constructing and elaborating rumors. In the case of online networks, we are drawn back to the original question of whether an information vacuum really fosters rumor, or whether in fact information overload or the suspicion of traditional, official sources might spawn or accelerate rumor, as well. This problem may be modern, but appears to have preceded the Internet. Rosnow and Fine (1976) suggested that "in a society with a free and divided press, different sources may contradict one another, which must inevitably add to the confusion and increase feelings of anxiety and fear."

Changing Information Ecology and New Media

There are other historical shifts since the heyday of rumor research that are important in thinking about the spread of

rumors besides the ease and opportunity provided by online communication. Renard (2005) asks us to consider that the ways in which truth and falsehood are currently differentiated, and the means by which we evaluate evidence in public discussions. Renard points to an increased acceptance of *cognitive relativism* where knowledge is 'neither objective nor final.' Reality and fiction are increasingly mixed together in many forms of popular culture, and this includes online interactions.

The Internet has also emboldened skeptics and debunkers of rumor and urban legends, and theoretically could facilitate antirumor activity on a broader scale. The computing revolution has also produced rumor modeling. Based on epidemiological research, modeling can produce practical insights about rumor intervention, and has shed some light on why some approaches work better than others, based on the formal properties of diffusion. Recognizing that attempts to defuse a rumor will include a time delay, Tripathy et al. (2013) simulated three antirumor strategies: the *delayed start* model, the *beacon* model, and the *neighborhood* model. Each of the models has 10 out of 22 'infected nodes' within a network that can spread to adjacent nodes, in the way that a well-circulated rumor can be repeated to a close associate. As the spread of the rumor in these formal models can be countered by the presence of antirumor nodes (representing effective debunkers or at least nonbelievers), the simulation can demonstrate upper and lower limits for saturation, and determine the most formally effective antirumor strategy in a network. The delayed start model launches an antirumor from a single node that travels to all neighboring nodes, after a time lag. This simulates the official response of a single or united authority to a rumor. In the beacon model, an antirumor campaign begins when an infected node in proximity is noticed by the preselected beacon. This model parallels the idea, already in practice in some places such as Barcelona, which trains 'sentinels' in communities that can be activated as needed to quell a rumor. The neighborhood model shows an antirumor campaign launched by random nodes. The delayed start model fared worst: even a rapid incline in antirumor activity allowed 70% of the nodes to be infected at a given time. The beacon model has a shorter time lag, and combated the rumor somewhat more effectively, but only reduced the saturation to 40%, even when the number of beacons was increased. The neighborhood model launches an antirumor process from random sentinels that are next to an infected node, rather than prechosen nodes. This model was the most effective; slightly better than the beacon model in its speed of the total episode. Tripathy et al. suggest that since beacon sentinels are chosen by authorities, there is too much network overlap in the pathways, and random selection avoids this problem somewhat. The analogy here is quite interesting: beacon (sentinel) social networks are perhaps more overlapping than we think. And yet it would be difficult to imagine harnessing an effective antirumor campaign by trusting random debunking. The authors suggest, as other rumor researchers have in the past, that a general social orientation to skeptical-mindedness in the face of unverified rumor might be the most effective approach – though the most ambitious. "The only way that rumors can be quelled," they note "is by using the power of social relationships."

Rural Geography

Jo Little, College of Life and Environmental Sciences, University of Exeter, Exeter, UK

Abstract

This article reviews the development of rural geography, focusing in particular on more recent work on the adoption of cultural perspectives to the study of rural societies and places. During the 1990s a significant body of research and writing in rural geography started to examine the social construction of rurality. This highlighted the importance of idyllic associations of the countryside and of the implications of dominant representations and meanings of rurality to the experience and well-being of rural people. It opened up a major direction in rural geography on the marginalization of 'excluded others' from rural life and on the nature and extent of inequality within rural communities. The article then goes on to illustrate this focus with particular reference to gender and the relationship between rurality and dominant constructions of masculinity and femininity, showing how idyllic rurality has been associated with particularly conservative and traditional notions of sexuality. Finally, the article highlights three current foci of research; food and security, well-being and animals, and explores their significance as central to the current development of rural geographies.

Introduction

Reviews of the history of rural geography as a subdiscipline have generally charted the development of research over time from regional land use studies through political economic approaches to the introduction of more 'cultural' perspectives. In so doing, they note the shift from highly descriptive, empirical research that tended to focus on rural areas in isolation, to more theoretically engaged studies, which connected with and drew on approaches from geography more generally (Cloke, 2006a; Woods, 2005). While this shift was (and remains) highly significant to the emergence of rural geography as a more legitimate subdiscipline with a valuable contribution to make to geographical knowledge and understanding, its importance is now well recognized. The purpose of this review is therefore to concentrate on more recent developments in rural geography and to discuss, in particular, work that has taken place in the past 10–15 years, and that has built on the recent cultural perspectives.

The article demonstrates through the discussion of work on the social and cultural construction of rurality and on the performance of identity, how rural geography has become more theoretically informed and confident. Perhaps somewhat ironically, the theoretical developments that have ensured rural geography's position within mainstream geographical thought, have also reopened questions about the robustness and relevance of the category 'rural,' which warn against an automatic association of particular characteristics and qualities with rural places and people (Cloke, 1997). This is somewhat reminiscent of former criticisms of rural geography when 'rurality' was frequently used as an explanatory variable. As the discussion here shows, however, more recent critiques of the notion of rurality have led, not as in the past to an abandoning of the concept, but to a more theoretically informed examination of the notion of space itself and of the coconstruction of space and space as relational concepts. The article begins by briefly examining the adoption of cultural geography perspectives in the study of the rural. It then goes on to consider in greater depth the subsequent research on rural identities and on the different and multiple experiences of rurality. The article then explores the growing interest in 'alternative' conceptions of rurality in which traditional constructions of rural places and people are challenged by new attitudes and ways of life within the rural.

The Legacy of Political Economy

During the 1980s the application of political economic approaches to the study of rural geography within Western economics had encouraged a focus on structural processes and inequality (Bradley and Lowe, 1984; Cloke, 1980). The development of rural regions and places was attributed to the uneven penetration of capital resulting from global patterns of investment and growth (Marsden et al., 1993; Urry, 1984). Agriculture in particular was seen to be driven by world markets and by political decision-making at an international level. Research in rural geography focused on the economic restructuring that resulted from the global movement of capital, identifying the implications for agricultural businesses at a range of different scales (see, in particular, Buttel and Newby, 1980; Goodman et al., 1987; Marsden et al., 1986). Research also paid attention to the effects of economic restructuring and uneven development on the lives of rural people, and particularly on the well-being or farming families. The major structural inequalities were shown to have very real effects, not only on the distribution of wealth among those working in rural industries but also on the broader access to and control of resources in rural communities. Thus the uneven development of capital was also seen to drive population migration and fuel a meaningful shift in the class composition of some rural areas.

During the 1980s and 1990s there developed a significant body of research and writing in geography and sociology on the nature and implications of an expanding 'new' rural middle class in developed, industrialized economies. Counterurbanization was identified as both a threat to and savior of a traditional rural way of life (Little, 1987; Newby, 1979). While appreciated for their commitment to rural living and for the new capital they brought with them, the middle-class 'incomers' were also blamed for contributing to the poverty of

'locals' by competing for scarce housing resources, neglecting the declining local services in favor of the more distant urban-based provision and resisting any new housing development that might help to increase the housing pool for the less well off. Such research provided important detail on the class changes taking place in rural areas, initiated by national and international patterns of economic change and an increasingly centralized system of decision-making (see Cloke and Little, 1990; Goodwin, 1998). Space (and rurality) was recognized as important (especially in relation to the unevenness of processes of development and capital accumulation) but there was a strong assertion within this research of the economic basis of social inequality. Research moved away from the idea that 'rurality' itself was the cause of the gulf between rich and poor, which had been identified as a significant characteristic of rural life but rather stressed the role of structural processes of class inequality in shaping the lives of those living in rural communities.

Counterurbanization, it was acknowledged, resulted in the gentrification of many rural communities, especially in more desirable commuter zones. Research documented the impact of gentrification on the class composition of rural areas and on their prosperity (showing, particularly in the UK, how wealthy migrants were creating middle-class ghettoes in many parts of lowland rural England). While initial research did recognize the impact of gentrification on the lives of the existing villagers, a more sustained focus on the differential experience of rural counterurbanization and associated issues of welfare and inequality came with the adoption of cultural approaches (Cloke and Little, 1997; Milbourne, 1997).

Cultural Geography and Neglected Rural 'Others'

A widely quoted springboard for new cultural approaches in rural geography came in the form of Chris Philo's 1992 article on 'neglected rural geographies.' In this short piece, Philo challenged the implicit and explicit preoccupation of rural geographers with the experiences of 'Mr Average,' arguing that both the content and the practice of rural geography were dominated by middle-aged, middle-class, white, males. He suggested that this emphasis be redressed in the study of 'other' elements of the rural population and that in so doing, researchers take on board the variety that exists in the composition and experience of the rural population. The fact that such variety has been 'hidden' from both academic and lay discourses of rural spaces reflects the dominance of particular constructions of rurality.

Following Philo's article, there was a concerted attempt by rural geographers to focus on the experiences of previously neglected, and frequently marginalized groups. Studies of, for example, young people (Jones, 1999; Valentine, 1997), black and ethnic minority people (Snipp, 1996), gays and lesbians (Smith and Holt, 2005), the homeless (Cloke et al., 2002) have helped to increase our understanding of the diversity of rural lifestyles. Moreover, many studies of 'other' groups within rural society have attempted to locate their findings within a theorization of difference and in so doing to draw on critical debates in social and cultural theory. These attempts to theorize difference and diversity have demonstrated the existence of multiple ways of experiencing rural spaces. They have also recognized that everyday experiences of those living in rural areas are shaped by the interaction of identity and place (Woods, 2011).

The development of work on 'neglected others' in rural geography was important in its focus on forms of disadvantage that were not entirely class-based. Previously political economy approaches had concentrated almost exclusively on poverty and access to economic resources in identifying marginalized groups and individuals (Lowe et al., 1987). At times poverty was used as a short hand to the consideration of groups such as the elderly and the unemployed but even so the class-based nature of the analysis still suggested that the main lines of difference within rural communities were economic. As the focus shifted beyond poverty to social exclusion, it was clear that the forces of division within rural society were much more varied than simply income, and that issues around inclusion and exclusion were as central to the welfare of rural society and individual rural residents as those of wealth and poverty.

The concept of social exclusion and the attention to marginalized or neglected 'others' provided rural researchers with far greater scope in identifying and understanding the divisions within rural society (Sibley, 2006). It encouraged attention to the detail of rural lifestyles and to the day to day and mundane experiences of those living in rural communities. Such attention allowed researchers to acknowledge that people's individual encounters with rural spaces and societies, their ability to 'fit in,' to enjoy and to flourish in rural areas were potentially determined by aspects of their identity that went beyond their economic prosperity and by the norms and attitudes that accompanied particular lifestyles.

Following the initial focus on neglected others inspired by Philo's article, rural geographers began to explore the broader ideas of identity in general. They moved from being solely concerned with a particular group experience to an interest in the ways different identities were performed and how they 'connected' with rurality. This led to a more dynamic understanding of the relationship between subjectivity and place and of the shifting nature of rural cultures and of the exclusion/acceptance of particular markers of identity (Cloke, 2006b, Woods, 2011). It also included concerns about 'intersectionality' in rural areas, that is, the ways in which experiences of some characteristics of identity were shaped and changed through an interaction with others (see Crenshaw, 1993). Increasingly, rural geographers became concerned about the sense in which the rural gave rise to particular performances of identity. Key questions about whether rural spaces and places created or reinforced certain ways of being, for example, gay or elderly or male. In other words, geographers recognized that at the center of understandings of the particular experiences of different groups was the role of rurality in those experiences. Such questions opened up debates on the *social and cultural construction* of rurality, a recognition that the rural is socially created and shaped, and that rurality is not simply a place but a set of cultural characteristics.

Rurality as a Social Construct

In showing that the experiences of different identities were profoundly affected by space and place, geographers began to

draw attention to the ways in which we understand rurality arguing that it was this cultural construction of the rural that lay at the heart of social exclusion as experienced by some groups of rural residents. The case was made strongly, for example, that the racism experienced by some black people who chose to live or visit rural areas of the UK derived either wholly or partially from the notion of the rural as a white space. The centrality of historical and traditional constructions of (white) rural communities and of the place of the countryside in notions of Englishness serve, it was argued, to exclude those who are believed not to belong in such a space (Kinsman, 1995). Similarly constructions of the rural as a place for families and close-knit social relations (as discussed further below) were seen to reinforce the strong presumption of heterosexuality as the only legitimate form of sexuality in rural areas and the consequent marginalization of gay and lesbian residents.

These dominant and, it was argued, highly powerful constructions of the rural have long featured in rural geographical research, collectively known as the 'rural idyll' (see Short, 1991; Newby, 1979) and comprising what in the UK in particular are very familiar characteristics associated with pastoral landscapes and communities. The characteristics of the rural idyll, while acknowledged to vary in some degree from place to place, have been shown to be not only well known but also very stable and enduring. The significance of the rural idyll became more prominent when research linked both the concept as a whole but also, on occasion, its constituent parts to experiences of social exclusion and marginalization (Bell, 2006). Constructions of rural places and societies were revealed as potentially responsible, in Western economies, not only for the general attitudes toward the countryside – in the UK in particular for the overwhelmingly positive representation of rural lifestyles – but also for more specific responses to social groups and events. It should also be remembered, of course, that in recognizing the power of idyllic constructions of rurality geographers also noted the ways in which they have been regarded as positive by many, particularly in terms of the endurance of the rural community. Representations of the rural community as supportive, friendly, and close knit have encouraged neighborliness and preserved expectations of social contact in a way that has shaped the behavior of, in particular, incoming residents (Little and Austin, 1996), ensuring the continued circulation of symbolic meaning of rurality.

The adoption of cultural perspectives in rural geography has had a major impact on the direction and content of research within the subdiscipline. It has also had a far-reaching influence on the methods employed by rural researchers; on the way data is collected, analyzed, and used. In common with other areas of geography, there has been a significant growth in the adoption of ethnographic methods in rural research and in the use of 'grounded theory' and while such approaches may have characterized some of the early rural 'community studies,' it is only recently that they have been more widely applied to a range of economic, environmental, and policy-based issues in rural studies. Those working on rural lifestyles and marginalization have argued, in particular, that a real understanding of the lives of those living in the countryside needs to emerge from the detailed analysis of their behavior, attitudes, and beliefs and that this can only be obtained through ethnographic methods. In addition, rural researchers have started to make use of a variety of other sources of data, drawing on art, literature, diaries, and other cultural artifacts, both historical and contemporary, in their work. With a shift in the methods used by (some) rural researchers has come something of a change in attitudes toward research. The sensitivity of work on marginalization and deprivation has opened rural geographers' eyes to the potential dangers of research tourism and encouraged them to think more carefully about the way their work may be used to the advantage or disadvantage of particular groups at particular times.

Gender and Sexuality in Rural Geography

One area of research and writing that deserves attention as emerging very strongly from cultural approaches in rural geography is that of gender and sexuality. The experiences of women in the countryside were referred to fleetingly in the early development of rural geography, in, for example, the discussion of labor relations within family farm businesses (Sachs, 1983; Symes and Marsden, 1983) and the sociology of the rural community (see Davidoff et al., 1976). The adoption of political economic perspectives in 1980s was accompanied by (limited) research on gender equality in rural areas and feminist perspectives started to debate the relative importance of class and patriarchy as systems of rural power relations (Little, 1997; Whatmore, 1991). Such work made relatively little headway in identifying women's inequality, however, since (outside agriculture) the plight of middle-class women living in rural areas rarely stimulated any great desire for change or recognition of marginalization. Hence, unlike in other areas of feminist geography, the distinct lack of political will for change among the majority of rural women (and men), acted to detract academic attention away from developing understanding of either the detail of women's lives or wider webs of gender inequality. It was not really until the introduction of cultural perspectives and the examination of the relationship between identity and the sociocultural construction of rurality that much attention was given to the gendered experiences of rural life.

In the early adoption of cultural approaches it was perhaps difficult to see rural women per se as a 'neglected other' in the same way as, for example, homeless people, since, as noted, the majority of contemporary women living in rural areas in developed countries are middle class, many are employed and exercise a significant level of choice in relation to their way of life (Cloke, 2003). It was, however, possible to identify a strong gender dimension in the social and cultural construction of rurality. Idyllic rurality held very firm ideas about the different roles of men and women and it was soon argued by geographers that, underpinning the dominant themes of community and family and the values of friendship, support and self-sufficiency, so powerful within the rural idyll, were particular constructions of gender (Little and Austin, 1996). Conventional rural life, it was argued, rested on the willingness of women in particular to fulfill particular roles, managing the continued existence and well-being of the rural community and ensuring the reproduction of the nuclear heterosexual family. It was recognized that rural women may feel marginalized not through lack of employment or income but rather

through an inability to comply with or buy into the dominant models of womanhood associated with rural life (see Hughes, 1997).

More recently, the debate on gender and rurality has extended to focus specifically on notions of femininity and masculinity in recognition of the importance attached to the dominant ways in which gender is 'done' rather than to fixed structures and relations of power. Research has drawn significantly on the work of social and gender theorists such as Judith Butler (1990) and Elizabeth Grosz (2005) in exploring how masculinity and femininity are not only constructed and represented but also performed in a rural context. Thus emphasis has been placed on the actual enacting of gender and of the values and expectations associated with sexual identities. Initial work in this area concentrated on key characteristics of rural masculinity among farmers and identified how qualities such as physical fitness and strength have come to define the identity of (male) farmers. The work of Brandth (1995), Saugeres (2002), and Liepins (2000) showed how the valorization of certain forms of masculinity within the performance of day to day agricultural tasks has shaped gender relations more widely within farming underpinning the designation of certain activities as 'men's work' and others as women's. Research has also shown how the performance of masculinity and femininity within agriculture is dynamic, changing over time despite their ubiquity. For example, Brandth and Haugen (2000) have noted how expertise in land-based professions in Norway (including agriculture) is no longer exclusively associated solely with men and that women are now acknowledged as having equal capacity for understanding and using the technical knowledge required to perform such expertise. In a different way, Trauger (2004) has shown that performances of masculinity and femininity within recent sustainable agriculture enterprises reflect far greater degree of equality than in more conventional forms of farming. She argues that the increasing number of such enterprises is potentially changing performances of masculinity and femininity in agriculture more generally.

Research on the performance of masculinity and femininity has also shown the ways in which gender identities continue to be shaped by traditional forms of heterosexuality in rural areas, to the exclusion of gay and lesbian identities. Little's (2003, 2007) work on rural dating and relationship formation among farming couples has again identified a range of characteristics and behaviors associated with dominant constructions of masculinity and femininity. For example, in seeking ideal partners, male farmers require women to be practical, homely, and 'low maintenance' and suggest that those who do not conform to more traditional forms of femininity will struggle to 'fit in' to rural communities and lifestyles. Women's expectations of their ideal rural partner also demonstrate highly conventional forms of masculinity in valorizing physical fitness, reliability, and loyalty. This, and similar research, demonstrates the continuing salience of tradition gender identities in the rural and that, even with some recent shifts to accommodate contemporary gender expectations (or, for example, women's involvement in paid employment), conventional ideals of masculinity and femininity continue to hold power in shaping rural social relations.

Recent Directions in Rural Geography

In the final main section of the article, I turn to emerging rural research and consider some of the topics that have recently come to the forefront of rural geography. Of course some of these areas of research are not entirely new in themselves but perhaps have gained a greater prominence in recent years and started to influence the shape and direction of rural research more broadly. In the remaining section, I briefly touch on three related issues of research; food and security, well-being, and animals.

Clearly, the centrality of the study of agriculture to rural geography means that food has long been a well-established topic of research. During the 1990s geographers became particularly interested in 'alternative' food production. They explored the increasingly high-profile concerns around food quality and environmental damage in the context of the use of new production methods inspired by the continued drive for increased productivity. Food safety became a major issue with producers and consumers responding to fears about the growing uncertainties associated with what were seen as 'unnatural' methods of both plant and animal reproduction. For rural geographers, this led to increased research specifically on food consumption (Goodman and DuPuis, 2002; Ilbery et al., 2005; Lockie, 2002) and on the choices being made in search of 'healthy' food produced through 'environmentally friendly' farming methods (Lockie et al., 2002). Research explored the implications of shifts in consumption toward organic and/or local food, fueled not only by the worry about food safety but also wider concerns among both the public and the farming industry about the ethics of food (especially animal) production and implications of new patterns of shopping for food and eating within the family (Jackson, 2010).

The interest in food safety has recently developed in more specific research in rural geography on biosecurity. This research has started to look at a variety of risks and threats to health of humans and animals connected to contemporary food production. Such research has opened up debates on the 'borderlands' (see Hinchliffe et al., 2013) of different global concerns in the production of food, and also questions about the ways in which 'life' itself is valued (Davies, 2013). Understanding the transference of disease together with broader questions about animal lives and welfare have led geographers to focus on what is meant by 'natural' and on how safety is ensured in a context in which nature itself is at risk and uncertain. The development of work from food safety to the broader notion of food security has acknowledged the ways in which questions of consumer preference and concern about food quality cannot be divorced from the more global issue of access to food – whether this be local and national concerns about the price of food and the quality of cheap food to international debates about the possible influence of climate change and limits to food production. Research here has only just started to engage with these questions but this is clearly an area where significant growth is set to take place in the next few years.

An interest in nature and its changing place in our lives also lies at the heart of the two other areas of rural geography research included in this section. Building on the work on food safety and drawing on more established and traditional

research in agricultural and rural geography, is a growing body of research on 'animal geography' (Buller, 2013, Philo and Wilbert, 2000; Matthews, 2012). As with the work on food security, the study of animals by rural geographers is not completely new (geographers have long been interested, for example, in livestock farming and in the contribution of animals to the rural landscape) but the current attention to animals is much more theoretically informed than in the past and has opened up new ways of conceptualizing animal–human relations, challenging normative and supposedly natural dualisms in the distinction of humans and animals. Animal geographies are also concerned with the materialities of how "exclusions, inclusions and physical distance between people and animals are managed and imagined" (Matthews, 2012: p. 127).

Work on animal welfare has drawn attention to ethical dimensions of new animal economies not only in relation to farming and food production but also in wildlife trade and biotechnical research. Parallels are drawn within animal and postcolonial geographies between the treatment of animals and that of colonized, indigenous people and researchers have talked about ways in which their research can give voice as well as speak about the 'other.' Such wok has raised methodological questions about the anthropocentric nature of research on animals and the power relations surrounding human–animal relations. As with work on food security and biotechnology, geographers have pointed to the rich potential of research currently being carried out and that still to be done, stressing that such research is highly important to future ways of living with animals.

A final area of recent research in rural geography that should be mentioned here is the relationship between health and well-being and rurality. The notion of therapeutic landscapes has received attention in the past but, as with the other areas mentioned specifically in this section, recent work has developed new ways of thinking about the topic. Thus recent geographical research has gone beyond the idea that certain environments produce or enhance well-being (by inducing calm and relieving stress, for example) to consider the coconstruction of place and health and look in more detail at the specific connections formed between people and landscape. Such work has drawn attention to the emotional and spiritual dimensions of being in landscapes and focused on the embodied connections made with the landscape/environment in the course of activities such as retreats (Conradson, 2005), yoga (Lea, 2008), and exercise (Little, 2012). Once again 'nature' has been shown to be at the heart of the therapeutic landscapes concept, in both a material and a spiritual sense, encapsulating the restorative qualities of the environment and the body. Therapeutic landscapes are thus regarded as those in which a connection can be made with nature in a return to a premodern engagement with 'pure' nature.

Conclusion

This short article has highlighted some key research in past and contemporary rural geography. It has resisted the temptation to provide a chronological review of the development of the subdiscipline in favor of drawing out more specific research topics. Rural Geography as a subdiscipline has gone through a number of cycles in recent years in which it's influence has waxed and waned within mainstream critical geographical thought. Following a period of relative stagnation, work on political economic approaches and then, more recently, cultural perspectives ensured rural geography acquired a central role in geography's development. More recently, perhaps, rural geography has lost something of its coherence and currency – a reflection perhaps of the changing place of 'the rural' in the public consciousness of those living in Western economies, in particular. Importantly, however, this relative decline in the coherence of rural geography is not reflected in academic research on 'the rural.' This continues to grow and develop in the focus on new and innovative topics and the search for original theoretical and conceptual debates to which rural geography and rural geographers can contribute. Such development has signaled a greater willingness to engage with cross-disciplinary research and to apply ideas and debates from beyond the narrow confines of rural studies.

Rural Planning: General

Hemalata C Dandekar, California Polytechnic State University, San Luis Obispo, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Rural planning is about developing and protecting physical and human capital and addressing the at times conflicting goals of economic development and resource conservation. It encompasses both the development of agriculture and natural resources – minerals, forests, fisheries, and scenery – and the conservation of these along with improving the access of rural people to infrastructure, education, housing, and amenities. Rural planning aims to bring about economic development, yet maintain the sustainability of renewable resources and reduce income disparities. It has been variously defined, including that it is place-based in focus and pertains to places that are nonurban, small town, and open spaces. The goals of rural planning post–World War II varied depending on the political ideology of nation states that formed the first, second, and third worlds. Forces of globalization during recent decades have erased many of the international differences in rural planning. The current global challenge of rural planning is to build up and diversify the rural economy, reduce inequity, and exploit the land and natural resources in a way that allows renewal and is sustainable.

Introduction

Elements of what is now termed rural planning can be found historically in the customary traditions and mores that organized agrarian societies, in all their diversity, throughout the world. Rules pertaining to land ownership and its inheritance, customs regarding cultivation practices including crops and tilling cycles, protective practices and rights in forest areas and common grazing lands, division of labor and gender responsibilities, water sharing rights and irrigation practices among others evolved to complement the specificity of social and political organization and climatic and natural resources of particular societies. They were fine-tuned to the microcontext of their constituent communities. Given civilization's historically rural roots, traditions were established which enabled populations to cultivate land and improve the quality of human existence but do so in balance with, and so as to sustain, the area's natural resources and land quality, the base of a traditional village economy.

Development Decades

Following the end of World War II, countries newly liberated from colonialism embarked on centralized, national development planning. Many of these countries were predominantly rural and so planning for rural development was often an integral sector of the national plan. Nations self-identified, or were identified as, first, second, or third world – a categorization some based on 'stages of development' and others on political ideology – to the left, right, or centrist. In the five or so development decades which followed World War II, these economic and ideological differences shaped individual countries' attitudes and approaches to planning in general and rural development in particular. Understandably, there was little consensus across nations on the goals of rural planning. For rural development, considered one of many interrelated aspects of planning, and having a decidedly spatial, locational (nonurban, noncity) connotation, the practices and objectives were many and varied. A general model for rural planning with a widely shared set of objectives and strategies to attain them was elusive. But the governmental concern about the rural reality, regardless of whether or not it was labeled rural planning, was predominantly about the agricultural enterprise, its efficiency, diversity, and ability to not only sustain the rural population but produce surpluses to support urban residents and for trade in world markets. In some locations, the focus was on the exploitation of natural resources more broadly (fisheries, timber, minerals). Their contribution to economic growth was a key indicator of success in the development planning model.

Impact of Globalization

Since the 1990s, the forces of globalization have impacted nations around the world in quite similar ways. They have also resulted, to a large extent, in creating similarities in thinking about, and visioning, rural planning efforts around the world. These globalization forces include an international acceptance of the idea of free global trade and capital flows; large-scale migration and immigration; a strengthening of connectivity and flow of information by way of technology such as the Internet which has served to reduce the 'friction of distance'; the increase in larger scale, often corporate agriculture; the increase in the scale and corporatization of natural resource extraction; a growing recognition of climate change; and the need to adapt and develop strategies which are sustainable, thus creating change in communities to make them more resilient.

There is an emerging 'one world' approach to planning one in which a first-, second-, third-world configuration no longer seems relevant. It is characterized by enhanced cross-fertilization of ideas and approaches, an increase in the flows of people, ideas, and culture around the world; and the evolution of national economies which privilege those with knowledge and technical expertise. In this globally integrated system, the characteristic attributes of first, second, and third worlds are juxtaposed within a country. They are to be found in

the location of people with resources and those without, within regions, within urban areas, and increasingly within rural areas too. Throughout the world, the notions of rural development have been transformed, and the issues of disparity and unequal distribution of assets and income are now emerging as priorities in the conditions of the rural. The industrialization of agricultural cultivation, processing, and natural resource extraction has disconnected the historically immediate and physical connection of rural communities from their economies. The emerging call in rural planning has been for developing sustainable practices to keep production in balance with replacement so as to maintain the resource base, strive for equity, and allow an adaptation to climate change.

Defining Rural Planning

Scanning the many variations of rural planning that are practiced internationally, it is possible to find some themes and an emerging congruence in aspirations. Rural planning encompasses policy and programs that explicitly or implicitly affect economic, social, and physical aspects of rural conditions. Rural planning has been defined as a set of two complementary concerns related to how people will earn a living, and how they will do it so that the natural, environmental, and social resources of a place will be conserved. Rural planning is about physical and human capital in regions that do not have the characteristics of urban places such as density, municipal governance, and a critical clustering of services and amenities. Rural planning addresses issues related to agriculture and also, more broadly, natural resources (fisheries, timber, and minerals). Traditionally, the concerns of rural planning were distinct from those of the urban, but increasingly, as the world has become more interconnected, there appears to be convergence in the identification of the most salient issues, and strategies and plans to address them. Increasingly in rural planning, in addition to the concern about equity and opportunity in urban versus rural contexts, there is a concern about the increasing economic gap between the affluent and those in jobs that pay minimum wages. Often these are related to, in countries of high immigration such as the United States and northern Europe, the legality and entitlement of residents who are documented and legal versus those who are not. Thus issues that were in the past thought to be concerns in urban contexts have increased in significance in rural contexts too and served to broaden the concerns of rural planning beyond agriculture to human resource development and infrastructure improvement.

Rural Planning in the Development Decades (1940s–80s)

During the development decades following World War II, approaches to rural planning in the United States, India, and China were based on quite differing ideologies about the role of rural areas in national development. The modern farm, which evolved in the United States with assistance from research at land grant universities and extension services funded by the government, was emulated worldwide. It involved the use of high-yield hybrids, fertilizers, pest controls, and extensive mechanization on a large scale to serve national and international markets. The approach of modernizing agriculture to attain economic development and growth in rural areas was tempered in Third World countries with a concern for attaining social justice through a redistribution of productive rural assets, and thus the benefits, accruing from development. Consequently, rural planning in second and third world countries explicitly embraced notions of equity and redistributive justice.

The heading 'rural planning' as a sector of government involvement is sometimes absent from plan documents in many countries. But policy and legislation related to sectors such as agriculture, transportation and communications, education, health and human services, and social welfare, which were addressed in national or state plans, have had far-reaching and profound impacts on rural areas. They have impacted the physical conditions of rural areas and shaped the availability of infrastructure and jobs. They have also determined the range and quality of services accessible to rural populations. When headings such as rural planning, rural development, and integrated rural development are present in plan documents, as discrete sectors requiring attention and having related funding lines in national and state budgets, these sectors are often defined in terms of engagement with social welfare agendas. The goals of such sectoral policies have often included statements about the need to redress inequalities in access to public services and redistributive justice. A broad definition of rural planning as encompassing policy that has both explicit and implicit intention to impact rural conditions, economic, social, and physical is adopted here.

During the formative period of the United States in the nineteenth century, agriculture production was a central element in its robust growth and development. Similarly, an agriculture-based economy and a predominantly agrarian population was the legacy of heavily populated, newly independent, countries like China and India, which faced the task of nation building in the second half of the twentieth century. But over the years, these countries have differed significantly in their approach to rural planning. The interventions of their governments in the rural sector define a spectrum of strategies and approaches, from total centralized control to indirect, market-driven change. Furthermore, these strategies, which took divergent paths at the start of nation formation, have over time sharply changed direction.

The United States, India, and China provide examples of countries that have developed rural planning-related policies based on quite differing ideologies about planning and the role of rural areas in national development. Their positions have ranged from the free market, laissez faire orientation typical of 'First World' countries like the United States to policies of 'Second World' countries like China that initially adopted a centralized, rural-cooperatives based model of rural planning from the former Soviet Union. China later embraced a market-based, global trade and industrialization focused approach, the success of which has made it a key competitor for dominance in the global economy. It has adopted policies that aim at radical reform and acquiesced to the notion of individual land ownership and private property.

Seeking a more intermediate path between these two extremes were countries like India, a founding member of the bloc of so-called 'Third World' countries that sought to chart

a distinct path, other than the United States or former Soviet bloc, first- and second-world approach to development. In the last few decades, it too has adapted and adopted policies that allow a greater play of market mechanisms in the rural, agricultural, and resource sector. Examining the development of the rural planning concept in countries like the United States and India provides a glimpse of the differing interpretations of rural planning that have been evolving around the world in countries where the government's ability to control, plan, and implement has been limited by, and has been cognizant of, the significant role of the private sector in the farming endeavor. Study of the China model provides an insight into the strengths and limitations of sustained, centralized efforts to control developments in rural economy and society.

The US Model of Rural Planning

The United States is acknowledged to be one of the most open and laissez faire economies in the world. Within the United States, the idea that attention needs to be turned specifically to rural planning is not a widely embraced concept. But models of economic growth that guide policy are accepted, and in these the agricultural sector is factored as an integral component of the national economy. Historically, US agricultural policy has defined and shaped rural conditions and had far-reaching consequences on the development of rural areas, but it has not been recognized as an instrument for rural planning.

This American ambivalence toward acknowledging the existence of rural planning is understandable given the historical antecedents. After the American independence, the feudalistic land law that prevailed under the British rule was replaced with a freehold land tenure system under which public lands were sold to raise cash for the new government. To facilitate sales, the US Congress ordered a land survey in 1785 that established a grid system of land division as the dominant pattern for the area west of Pittsburgh. Its indelible stamp ordered the transportation and communication systems and helped give shape to rural administrative areas. Subsequent land laws and purchase allowed "Such a mass distribution of land to those who tilled the soil was unique in the history of the world up to that time" (Cochrane, 1993, p. 57). The philosophy of land ownership as vesting freehold in an individual, and the establishment of a unique American tradition of independent and self-reliant farm families scattered in a regular pattern, each in isolation, on their own individual pieces of land, has perhaps contributed to a national antipathy to identifying government interventions as responsible for rural development. Nonetheless, these early interventions shaped the rural context, with plans that were not always openly agreed to or publicly articulated and embedded it with desired outcomes that might have been contested if formally acknowledged in planning documents.

The movement of the US agricultural enterprise from the subsistence cultivation of the pioneer to the high-tech, mechanized, computerized, agro industry of today's corporate farm is not the product of free-market forces but of significant government actions. The role of the government in shaping US farming is noted and generally accepted in the literature pertaining to American agriculture (Rasmussen, 1960; Cochrane, 1993; McConnell, 1953). They delineate a broad and inclusive set of categories in which government has been active, establishing that it has been involved in almost every aspect of agricultural development. With the passage of the Agricultural Adjustment Acts of 1933 and 1938, the Department of Agriculture has supported and managed agricultural production pursuing policies affecting both the supply and distribution systems of agricultural production (Cochrane, 1993; pp. 140–143).

Modern Farming in the United States

Government activities in the transport, research, and education sectors have transformed American agriculture from subsistence to cash cropping for regional and national markets and later to capital-intensive agribusiness. Significant government support of educational and research institutions assisting in agricultural development through scientific and technological innovations has been sustained for more than a century. The Morrill Act of 1862 enabled government to fund land grant colleges in each state and the Hatch Act of 1887 allowed annual allocations for state agricultural experimentation stations devoted to basic agriculture research (Rasmussen, 1960). The impact of this activity on shaping the scientific base of modern American farming and increasing productivity and efficiency was significant and to date has had resonance and wielded influence around the world.

In response to the worldwide Depression of 1929, New Deal agricultural economists created the Agricultural Adjustment Acts of 1933 and 1938 to set the price and allowable level of farm production. The central theme in these legislative efforts was to stabilize agricultural prices and income by offering subsidy payments to farmers to reduce production, price support measures, and commodity storage. In the postwar period from 1945 to 1975, the modern farm evolved in the context of rapid advances in national/international transport, the emergence of the United States as a major world power, and the corresponding change in its domestic and foreign policy, and tremendous advances in scientific/technological farming in the United States including development of high-yield hybrids, fertilizers, pest controls, and extensive mechanization. The modern farm featured large-scale production for national and international markets. Cultivation for sale rather than family subsistence became the central production objective of the farm enterprise. However, the ideological underpinnings of the earlier time of minimum government control in the farm enterprise persisted. There was support for government to be an agent responsible for presenting new options and alternatives which might voluntarily be subscribed to, or not, by the American farmer.

Corporate Farming in the United States

A shift from modern to corporate farming after 1975 was triggered by changes in the role the United States played in world affairs and the tack it took with respect to its foreign policy following World War II. The United States emerged as a leading proponent of global free trade. This posture meant that the highly efficient farms in the United States began to function as the 'world's breadbasket.' Farmers produced and

exported crops to India, Russia, and other countries when they faced domestic shortfalls in food production. Advances in national and international transport aided this expansion of the market. 'Green revolution' technology packages of high-yielding hybrids, superfertilizers, and pest controls were developed leading to unexpectedly large crop yields. Specialization and monocrop farms become common. Although energy intensive in their use of new products and machinery, they were viable as energy costs were kept relatively low by the government. A process of consolidation of family and modern farms into larger and larger vertically and horizontally integrated corporate entities occurred. The resulting corporate superfarms have changed the rural landscape tremendously as fewer and fewer farms account for more and more of the total farm sales and total farm profits in the United States. This concentration is apparent in the fact that 2% of all farms in the United States produced 50% of total farm sales in 1997 and by 2007 some 187,816 of the total 2.2 million farms in the United States accounted for 63% of sales of agricultural products and 125,000 farms produced 75% of sales.

Services-Oriented Rural Planning

In the 1980s and 1990s it has been increasingly obvious in the United States that although the link between agriculture policy and rural planning has traditionally been very strong it may be less important in the emerging 'global' economy of the twenty-first century. Today the link that needs to be forged for rural planning is with economic sectors such as manufacturing and services. The emerging 'new economy' is based on the growth of the service sector and geared to the information industry that has centralized population in metropolitan areas. The impact of this centralization on populations that remain rural and dispersed is significant. For example, in rural areas, public services in education, health, and social welfare provision are of lower quality than in the metropolitan areas. Currently, US rural planning efforts have focused on providing quality services despite the delivery difficulties posed by lower population densities that mean that greater distances must be covered to reach targeted rural populations. A second strand of rural planning pertains to national settlement patterns and the belief that it is important to maintain numbers of people in rural areas. Planning efforts creating rural enterprise and empowerment zones have involved job training programs as an economic development policy to attract entrepreneurs. The second element of this strategy aims to reduce costs for entrepreneurship in rural areas by programs that make capital available for business development. The scale of such efforts is, however, quite modest. Finally, the current paradigm of rural planning focuses on equalizing rural communication and infrastructure with those of the urban. Supporting the expansion of Internet and high-speed communications links, wireless, and satellite connections all aimed at linking dispersed populations are an integral part of this agenda.

The Third World Approach to Rural Planning

Numerous countries attained independence from European colonial rule at the end of World War II. Some, like the Peoples' Republic of China, became Second World countries that adopted planning models emulating Soviet-style control by a strong central government. Another bloc of countries attempted to forge a separate third path to development differing from United States-style capitalism and Soviet-style socialism. This Third World forged constitutions endorsing centralized planning by government to attain modernization by facilitating rapid industrialization of both the private and public sectors. In these models, rural planning tended to be a key element in national economic development. Rural planning measures aimed not only to increase production but also to redistribute wealth on the grounds of social justice and human welfare. The latter provided legitimacy for governmental planning which was essential in countries recently released from colonization. Furthermore, the majority of these nations' populations were rural. In approaching the development of rural areas, many of these countries emulated the US model. They aimed to increase and improve agricultural production through the application of scientific research that was to be developed, disseminated, and implemented in farming practice through agricultural extension services. This was seen as the modern way for rural planning to support national economic development.

Third World countries aimed to use agricultural production to raise capital for industrialization and the development of related infrastructure, as well as for the provision of urban- as well as rural-based populations. However, they tempered their desire to increase agriculture production with the broader objective of bringing about an increased living standard and quality of life for economically disadvantaged populations in the countryside. Their emphasis on rural planning for human development reflected their recognition that the majority of their populations were rural, asset poor, involved in subsistence production, and members of lower-status social groups or social structures that were feudal in character. Over time, these countries evolved a planning model for 'integrated rural development' that recognized gender and class differences and attempted to address social inequalities in access to rural resources, a process differentiated from earlier production-oriented agricultural development models. This approach to rural planning attempted to combine and balance between agricultural and economic development and social welfare and redistributive justice.

The Indian Model

At the point of independence from British rule, India embraced rural planning directly. Initial Indian national planning efforts to achieve rapid socioeconomic change concentrated on industrialization at chosen metropolitan centers, on the assumption that the benefits would 'trickle down' through the economy. Planners believed that although initially benefits would be concentrated in the core cities, they would spread to rural areas. However, they also recognized the need to promote complementary rural planning to reduce existing and anticipated urban–rural disparities in wealth.

Rural planning measures in India conspicuously emulated the US model of agricultural development. They included irrigation projects; the promotion of scientifically developed

cash crops through the provision of improved seeds, equipment and fertilizer (the so-called Green Revolution approach to making agriculture productive); providing credit for agricultural investments to stimulate agricultural production; and the establishment of a system of extension services to introduce scientific farming techniques at the village level. They also regulated markets to stimulate trade in agricultural commodities; invested in roads and communications; and founded cooperatives to buy and sell agricultural products and facilitate the marketing of goods in rural areas.

The national policy of investing in industry and commercial agriculture increased the gap between those involved in the corporate formal sectors of the economy, urban and rural, and those in the informal, traditional, subsistence sectors. Rural landless and land poor, squeezed out of traditional positions in village society, migrated to the city in unprecedented numbers. Cities were unable to accommodate the massive influx of displaced, often unskilled, rural laborers and their families and urban environments deteriorated as slum settlements of the poor proliferated. Responding to this phenomenon inspired a new set of rural planning policies. Stemming migration to the city by improving rural life and diversifying the rural economy emerged as prime planning objectives. Making rural living more attractive included provision of postal service, healthcare facilities, clean drinking water, and electricity in the countryside. As this policy evolved, its objectives also expanded to include increasing equity and distributing the benefits of development to the poor more explicitly. This change inspired such planning measures as putting a ceiling on individual land holdings, reforming tenancy to enhance the rights to the land of those who cultivated it, initiating programs to support traditional artisans with better tools, establishing credit and marketing networks to allow them to compete with industry or at least sustain them until alternative jobs were created. Finally, the Indian government emphasized free, mandatory elementary school education throughout rural areas to improve skills the poor needed to compete for development benefits.

In 1976, A.T. Mosher an international agricultural development expert summarized the various phases of Indian rural development planning in *Thinking about Rural Development*. He described some common characteristics:

- recognition that although economic development is important it is not an essential precondition to the social transformation that is considered the central objective of a rural development strategy;
- attention to increasing efficiency with the technical revolution of fertilizers and high-yield varieties of cereals; the attempt was to boost both food grain production and commercial crops and monoculture production of commodities for which there was an international market;
- development of programs that addressed equity and asset redistribution; and
- enhancing rural citizen's participation in the evolution of locally appropriate planning programs.

Current Priorities and Approaches in Rural Planning

Mosher's insightful observations made several decades ago remain salient internationally in the current discourse on rural development and rural planning. Elements of the phases of rural planning policy and objectives in India – moral and social transformation, economic efficiency, redistribution and social justice, and popular participation in decision making – are to be found in the current rural planning approaches of many countries around the world although there is of course a great deal of variation in policy, in emphasis, and in the capacity to implement. There has emerged one key and significant addition to the above list of characteristics or rural planning discourse, that of the notion of sustainability – social, resource-based, and economic – of adopted approaches to, and practices of, rural planning.

Rural planning oriented to improving physical infrastructure and the quality of life for rural populations was an important policy agenda in developing countries in the earlier periods of their postindependence histories. More recently, as rates of urbanization have remained high, these countries and cities have experienced hypergrowth (despite efforts to stem rural migration and population increases); rural planning in many countries has become a lower priority endeavor. In the worldwide liberalization of economies since the 1980s and 1990s, attention has been focused on world cities of over 10 million people, and, as a result, notions of intervention in rural areas to improve rural conditions have been given far less significance.

A questioning of 'top-down' science-driven Green Revolution strategies and of intensified agricultural cultivation has emerged as the negative impacts of this approach on the natural environment have become increasingly apparent. A call for 'sustainable agriculture' is heard and policy to achieve it is proposed (Cochrane, 2003, pp. 65–82, 98–101). The notion of sustainability in agriculture, forestry, mining, and other interrelated sectors is also apparent. The policies and plans which are suggested to achieve this goal of sustainability incorporate some practices and values of earlier traditional modes of cultivation.

The concerns about the long-term negative impacts of the Green Revolution and its consequences have surfaced in many parts of the world. They are related to degradation of soil quality; depletion of groundwater tables; the salinization of land; and high fertilizer use and pollution of water systems from agricultural run-off. The long-term sustainability of modern agricultural cultivation on prime land is questioned, and as supply of such land is exhausted, concern about the viability of applications of this technology package on poorer quality, more fragile lands is raised. There is a rising concern about genetically modified crops entering the food system of human populations. These concerns have led to calls for a modified, mixed approach to rural development that recognizes traditional, sustainable practices. In contexts of risk-prone environments, development planners are describing a need for a rural planning strategy in which 'top-down' science-driven Green Revolution strategies of intensifying agricultural cultivation are tempered with the understanding that can be attained by tapping the knowledge of rural cultivators who are following traditional, self-sustaining forms of agricultural production (Pichón et al., 1999). This position, labeled 'sustainable agriculture,' has stimulated rural planning efforts based on more traditional modes of agriculture (National Research Council, 1989). The task of helping rural places has

been defined as a set of two complementary concerns related to how people will earn a living (Lapping et al., 1989) and how they will do it so that natural, environmental resources will be conserved (Sargent et al., 1991).

In the First World rural planning is coming a full circle. Rural areas are serving as an escape and retreat from the pressures and stress of cities for the affluent and as a source of raw materials and natural resources for urban areas and industry. The corporatization and large-scale production of agricultural enterprises has required less labor and resulted in fewer jobs in rural areas. From a 'universalistic' modern science-driven notion of development and progress, there is a renewed orientation to the specificities of the local, rural, asset base of both physical and human capital. Rural planning is construed to involve development and support of agriculture and a broader set of natural resources including fisheries, timber, and minerals and the conservation and protection of these resources with a view to sustainability and conservation. The challenge for rural planning has been to answer the question of how to rebuild a local economic base and sustain rural communities. Some high-amenity places – coastal communities, beach-front towns, and sites of historic and scenic natural resources such as lakes, mountains, and forests – have capitalized on tourism and amenity migration of higher-income residents.

The literature on planning amenity-led development is substantial (Marcouiller et al., 2002). In many communities, along with amenity migrants, in parallel, has been the in-migration of low-wage workers filling jobs to provide the services that amenity migrants need and demand. High housing costs in these amenity-rich locations compel these service workers to commute and find affordable housing and make community in settlements that are away from the amenity core in less desirable locations (Nelson and Nelson, 2010). They bear the cost of travel time and expense of their commute for work. This has raised equity issues.

Other options for rural development have included efforts to establish rural manufacturing and back office support such as call centers and agricultural processing such as meat packing plants for poultry and beef, all of which also tend to create a majority of jobs for low-wage workers. These trends were recognized in the 1994 creation of USDA Rural Development to administer nonfarm financial programs for housing, community facilities, water and waste disposal, rural businesses, and rural electric (Rural Cooperatives, 2004). Rural policy in the twenty-first century also acknowledges the need to support human resource development, improve education levels and skills, enhance telecommunications infrastructure to improve connectivity and opportunity for rural residents (Marshall, 2001).

Today, the first/second/third world configuration that shaped mid-twentieth century rural planning strategies seems less relevant. First and third world-like economies coexist in cities around the world, not only between nations, and, increasingly, that duality is emerging in rural areas too. This trend is global. A 'one world' approach to planning in general is emerging with the forces of globalization that are creating systemic similarities around the world. The cross-fertilization of ideas and approaches has been ever facilitated by the increased flow of communication that technological innovation has enabled. In much of the developing world, facing the waves of change engulfing countries in the throes of economic liberalization, rural planning has been placed much lower in priority to programs that address issues of rapid urbanization and globalization. Thus programs related to social justice, participatory decision making, sustainability, and the environment have taken second place to economic transformation of rural production. But there is a concurrent literature and policy emphasis in rural planning that is place-based and enjoying resurgence due to concerns about sustainability and resilience of settlements and communities (Olfert and Partridge, 2010). Thus, the inherent tension between growth and sustainability that emerged toward the latter part of the twentieth century in the thinking about national development planning is increasingly apparent in the ways that rural planning is currently being defined and framed around the world.

Rural Social Work

Margaret Alston, Monash University, Melbourne, VIC, Australia

Abstract

Rural practice is a critical emerging social work field. While social workers have always worked in rural areas, climate change, environmental disasters, and the ongoing impacts of globalization are placing significant stress on rural people and communities, and leading to a new evaluation of the environment and its significance for social work. This article examines rural policies and practices that challenge and disrupt effective social work services into rural communities. It also highlights that rural social workers adopt innovative and creative practice models to deal with isolation and other barriers, thus creating the space for a reimagined and radical social work.

Introduction

Rural social work is a critical, and increasingly prominent, field of practice. While social workers have always worked in rural areas undertaking a number of roles in a variety of areas of practice, two key factors are shaping a new form of practice interface – the link between environmental crises and disasters and globalization. The first relates to ongoing climate and environmental disasters and includes both slow onset events such as droughts and desertification, and cataclysmic events such as earthquakes, fires, floods, river erosion, and mud slides all of which have had major impacts on landscape and significantly changed the social relationships and industry base of many rural communities. Add to this globalization – a process that is drawing industry, people, and wealth away from rural areas for which the result is environmental, economic, and social decline overlaid with climate uncertainty leading to stressed and highly vulnerable communities.

In this article I present the view that rural social work is a complex field of practice requiring a critical understanding of the link between people and their environment shaped by the social, economic, environmental, political, and cultural factors that identify rural spaces. Across the world rural areas are sites of ongoing change, typified by growing uncertainty, food and water insecurity, and evidenced by increased poverty, an aging profile, and inefficient or nonexistent services. In this context, social workers must be equipped with a rich understanding of the link between people and place (Zapf, 2009) and the structural inequalities that reduce the political power of rural people to address their disadvantage.

Defining the Rural

Since 2008, and for the first time in history, a majority of the world's population now resides in urban areas (UNFPA, 2007). Politically, this growing urbanization reduces attention to, and the resourcing of, rural areas. Nonetheless, rural places are as diverse as city suburbs and this makes an adequate definition of 'rural' very complex – a conundrum that the UN largely leaves to nation-states. The way rurality is understood and experienced in different countries is shaped by social, cultural, and political factors (Pugh and Cheers, 2010). Most see the 'rural' as places 'out there' away from the cities, a view that leads countries such as Australia to define rural spaces in terms of what they are not – that is, anything that is 'nonmetropolitan.'

Attempts at conceptualizing rurality more carefully usually center on one of three bases: a spatial element that draws on population numbers and size of communities as a unique indicator (see, for example, Hugo, 2005); an economic definition that is based on the industry base of the area (typically agriculture or mining) (Alston, 2009); or a reliance on sociocultural factors that denote somewhat controversially that rural communities are typified by shared relationships and values – a rural idyll that has often been portrayed as morally superior (Leipins, 2000). None of these definitions are entirely satisfactory either together or in isolation. Perhaps it is best to adhere to Rios's (1988: 1) comment that *people know when they are rural!*

Setting and Context

Nonetheless, the inherent complexity of rural areas should not be diminished. A common reminder in rural literature for practitioners and policymakers is that "if you've seen one rural community, you've seen one rural community!" (Raitano, 2010). In other words, rural communities are never the same, varying as they do in size and scale, in industry base, in population composition, in landscape detail, and in the degrees of socioeconomic complexity. Nonetheless, the further a community is from a capital city or regional base, the less likely it is to be economically viable, the less likely it is to have efficient, available services, the more likely it is to have an aging and masculinized population profile, the more likely it is that working aged people will have at best a precarious attachment to the labor force, the more likely it is that mortality and morbidity rates are higher than in urban areas, and the more likely it is that there are large numbers of socially excluded people including higher numbers of indigenous people (Cheers and Taylor, 2005; Foster, 2007; AIHW, 2008; Alston, 2009). The reasons for these trends include rising levels of poverty, the largely agricultural base in more remote communities, patrilineal inheritance practices in agriculture, the out-migration of young people for work and education, the greater out-migration of young women, the decline in services as these

are shifted to regional centers and cities, the loss of jobs and businesses, the higher rate of risk-taking behaviors, and the greater exposure to environmental hazards (Alston, 2010a, 2009; Alston and Kent, 2006; Gray and Lawrence, 2001).

Where these trends may vary, if only temporarily, might be when a mining industry is established and a quick development of workforce occurs. These rapidly expanding mining communities can be stressed for different reasons including a fly-in fly-out, largely male workforce, low levels of services, high housing prices, a skewed labor force where lower paid jobs outside the mining industry can be harder to fill, (Petkova et al., 2009) and high levels of environmental degradation (Dominelli, 2012).

Social workers will note that the challenging dynamics in rural communities described above provide fertile ground for a range of social outcomes and emerging social problems. These include complex multifaceted social problems, involuntary separation of families if a family member is forced to out-migrate for work and/or education, the precarious nature of employment options, health issues, aging, and poor access to services. When we add climate uncertainty and globalization, these problems are magnified (Alston, 2009; Alston and Kent, 2006; Gray and Lawrence, 2001).

Critical Factors – Climate Uncertainty and Globalization

Global warming is having an unprecedented impact on our environment, landscape, and social spaces and cuts deeply into rural areas. Slow onset events such as drought and rising temperatures affect cropping cycles, the types of crops that can be grown, the capacity of farmers to produce an income, and both food and water security (Garnaut, 2008, 2011). Cataclysmic events such as cyclones, fires, and floods cause deaths and injuries, decimate communities, affect agricultural and fishing industries, destroy infrastructure and income generating activity, and change the landscape, often irrevocably (Opdam et al., 2009; Campbell, 2008; Proudley, 2008).

Across the world, the increasing frequency and intensity of climate and environmental disasters are deeply affecting rural people and places. A range of recent disasters causing major social trauma include flooding in the Philippines (Tatlonghari and Paris, 2012), bushfires in Australia (Hargreaves, 2012; Proudley, 2008), drought and cyclones in Bangladesh (Alston, 2013), hurricanes in the US (Enarson, 2009), rising sea levels in the Pacific (Alston and Vize, 2010), and earthquakes in Japan (Barusch, 2011) and New Zealand (Lynch, 2011). Many of these events are located in rural areas where whole communities are affected by trauma and tragedy. Social workers should note that climate change is not only causing environmental disasters, but also immense social distress and thus is a human rights issue (Tester, 2012).

Climate change events are but one of a suite of social, economic, and environmental factors that will impact on food producing areas. With the world population expected to rise from 7 thousand to 9 thousand million by 2040 (The United Nations Secretary General's High-level Panel on Global Security, 2012), creating significant consequences for food and water security; a growing middle class in Asia and the subcontinent placing more pressure on food production (Gillard, 2012); predicted fuel shortages (Newman et al., 2009); conflict and political instability in many areas; and massive people movements – resulting from these factors (McAdam, 2012), the stresses on the environment and on people in rural areas are magnified. By 2030, the world will need at least 50% more food, 45% more energy, and 30% more water despite the fact that food production cycles are interrupted by climate events (The United Nations Secretary General's High-level Panel on Global Security, 2012). Rural spaces will become the locus of major transformations, instability, and ongoing environmental pressures at the same time as the world requires significantly more food and water resources.

Globalization, or the instigation of a global marketplace creating global interdependencies, is drawing wealth and capacity from the local to the global arena (Gray and Lawrence, 2001). In the process, it is providing a compelling influence for people to move to cities to work, often in jobs based on the knowledge economy. Globalization has resulted in significant changes in rural areas as agricultural producers are now dependent on a world market, their income subject to global circumstances and their capacity to respond to higher productivity demands diminished (Lawrence, 2005). Without adequate policies and programs, communities plagued by poverty, climate challenges, and out-migration pressures are ill-equipped to address future uncertainties.

Part of the problem is that there are limited attempts to create complex interlinked rural policies that cross-portfolio areas. Thus, it would seem evident that enhanced information technology will assist health delivery in isolated areas with low levels of services. Yet, in Australia at least, many areas are without mobile phone coverage and significant portions of rural Australia are not covered by technology that will assist service delivery. Additionally, with the centralization of services away from rural areas it would seem obvious that cheap, readily available transport is necessary to ensure that access is not corrupted by distance. Again, this is not the case, leaving the impression that, as the political influence of these areas decline, rural communities are abandoned and the citizenship rights of rural people are overlooked under the banner of efficiency and neoliberal economic philosophy.

Rural Policy

The decline of the welfare state and the rapid rise of neoliberalism across the world have resulted in a downgrading of social supports at the same time as principles of individualism and self-sufficiency are championed by governments. Neoliberalism is very much focused on market values, leaving those outside the labor force in an increasingly precarious position. Thus the aged, disabled, carers, and many rural people with few job opportunities are at risk. While economic neoliberalism dominates in Australia, the development of supportive rural policies and programs varies across the world. Many nations like Australia are committed to an economic rationalist orthodoxy that blinds attention to the human rights of people most affected by global challenges.

Climate variability and policies designed to address these challenges are a good example. Defining climate change as one

of the greatest moral dilemmas of our time, Molnar (2010: 12) reminds us that rural people will be most adversely affected by climate events and by policies aimed at climate change mitigation:

> the distribution of rewards from climate change mitigation is broad and diffuse; the distribution of costs, compromised livelihoods, and community disruption often is focused. The opportunity for institutional recreancy through benign neglect or active exploitation of less-populated locales in the conduct of climate change mitigation are many.

Neoliberal- and efficiency-based policy drivers are evident in many countries through processes of privatization of services, the removal of government from the front line of service delivery, regionalization and centralization of services such as health and hospitals, and the introduction of user-pays principles to basic service structures (Alston, 2009). These policy principles, reliant as they are on a critical mass of service users and a profit motive, inherently disadvantage rural people. Centralization of health services, for example, results in rural people needing to travel long distances for basic services such as birthing, cancer treatment, and other specialist attention. This has significant gendered impacts. In the case of birthing, women are left in highly vulnerable situations often needing to travel long distances in labor (Dietsch et al., 2008), and rural women also may opt for radical cancer treatments such as mastectomies rather than less invasive but more time intensive treatments (Alston and Kent, 2006). Mental health services for men that address issues associated with rural decline are also lacking (Alston, 2010c). Major cutbacks in public spending and a profit rationale for service delivery in countries such as Australia, where vast distances separate people from services, result in a significant impost on the human rights and citizenship rights of rural people. Inevitably this results in a reduced number of welfare services, declining infrastructure and transport, restricted employment opportunities, and growing poverty – problems that are largely invisible to the general population (Pugh and Cheers 2010). The loss of services also means a loss of a professional class of health and welfare workers, and those that remain, experience significantly increased workloads.

Nonetheless, rural policy across the world varies from an overreliance on the marketplace to determine outcomes and futures, to one where policy incorporates inclusive practices and equity goals. While the United States and Australia favor a market-based approach, many European Union countries and the United Kingdom have introduced a greater focus on social equity (Shortall, 2008). The distinguishing feature of this differentiation is that countries such as Australia and the United States tend to conflate rural policy with agricultural policy, limiting their vision to productivity gains and technological advances in this industry (Alston, 2010b). The inevitable consequences of these policies are that agricultural producers are on a constant treadmill, needing to work harder and faster and to continually expand their operations. This philosophy has dire consequences for rural areas. It results in larger farms and a declining number of small farms or the gentrification of rural areas, loss of rural families and thus a rise in commuting families in areas close to urban centers, lower numbers of school children and hence a loss of teachers and services such as school buses, lower numbers of people available for sports teams and social activities, a spiraling loss of social capital (Lawrence, 2005), higher levels of racism in rural areas, and a lack of human rights in countries such as China where registration under the hukou system reduces the rights of rural people to education and employment relief (Caixiong, 2013).

By contrast, EU and UK policies have given a greater focus to people and place, adopting a *territorial* rather than a *sectoral* approach, putting emphasis on the inherent complexities of rural areas and the diverse nature of the whole community rather than on the agricultural base as the leading driver of policy (Warner and Shortall, 2008; Shucksmith, 2008). Policies in these areas tend to rest on a notion of sustainable development with sustainability recognized as incorporating social, economic, and environmental aspects.

The principles underpinning sustainable development draw from the landmark Brundtland Report (1987: 9) that defined sustainability in terms of intergenerational equity – meeting the needs of the present generation without compromising the ability of future generations to meet their own needs. Subsequently there has been a significant focus on social sustainability and socially sustainable communities (Cocklin and Alston, 2003). McKenzie (2004: 18), for example, defines socially sustainable communities as *equitable, diverse, connected and democratic and providing a good quality of life*.

The introduction of sustainability as a basis for rural policy has led to what Marsden (2009) terms place-making and Shucksmith (2009) place-shaping – a recognition of the needs of the whole community rather than just the agricultural sector. Place-shaping policies acknowledge that a socially inclusive community requires services and supports that aid integration and resilience. However, while globalizing forces and environmental disasters continue to drive rural change, territorially focused policies shine a light on social complexities, the need for alternative industry jobs and service infrastructure, and recognition of the inherent rights of citizens.

Social workers should understand the principles underpinning policies that affect their rural areas and be prepared to advocate for social implications to be considered, for cost-effective services to be accessible and available, for equity, and for the rights of rural people to be addressed in policy determinations. Reflecting on the nature of social work practice, bringing the voices of the marginalized to the policy table, and reflecting on the rights-based focus of services and service structures are a critical feature of the work of rural social workers.

Rural Practice

The complexities of people and place and the impact of globalization, increasing poverty, aging, and service decline are reshaping rural social work as a unique and evolving field of practice – one that Dylan (2012: 79) terms *radical, sustainable social work practice*. Rural social work practice is distinguished by its setting and context (Pugh and Cheers, 2010; Maidment,

2012), and, as with all fields of practice, it is useful to approach rural social work with an understanding of professional aims. Payne (2000) suggests a contemplation of whether their purpose is to ensure that the continuance of the preexisting (potentially inequitable) social order, to assist and empower people to take control of their own lives (with limited resources), or to facilitate transformative social change (see for example Pelling, 2011). Picking up on this theme Dominelli (2012) notes that environmental crises may provide the space to challenge structural inequalities through a new approach to rural spaces. Further she reminds us (2012: 3):

> Contemporary social work has a vested interest in attending to environmental issues as an integral part of its daily remit if it is to retain its currency in contemporary societies [and] emphasise the social issues that people have to resolve in the twenty-first century…

These social issues are exposing the rural context to increased scrutiny from governments and NGOs. Social workers are implicated in crisis interventions and reconstruction activities following sudden onset environmental disasters and conflict situations, and in rural places subject to ongoing but slowly evolving changes and can make a significant contribution to policy and practice advice.

Australian social workers, for example, have been deployed in large numbers to areas within country affected by floods and bushfires, and have been prominent in postdisaster work in areas across the Asia Pacific region, most recently including in Christchurch and Japan following major earthquakes, in Bali following a terrorist attack, and across several Pacific regions following the 2004 Tsunami (Hargreaves, 2012). It is not unusual for large numbers of social workers to be sent by the Australian government within 24 h of a crisis situation. This work usually short term – involves long, harrowing hours of work – is focused on crisis intervention and reestablishing communities, and requires collaborative work with other professionals and groups. Social workers are also engaged in medium and long-term reestablishment phases of postdisaster situations, but it is the immediate aftermath where social work action is most visible (Hargreaves, 2012).

Rural social work is not just about postdisaster situations. Social workers in rural areas work in a number of fields including health, mental health, child protection, community development, as well as a range of other areas in government, nongovernment, and private organizations. Their work incorporates all types of practice including casework, group work, advocacy, community development, research, and social activism. Most rural social workers are generalists, working across a number of areas with a strong focus on community development (Locke and Winship, 2005) in practices that Maidment (2012) describes as generalist and generic.

Pugh and Cheers (2010) suggest the importance of informing rural practice with an understanding of the history of the community, its informal politics, local networks, and local knowledge – a position supported by Locke and Winship (2005), who also note the importance of cultural factors. This adds significant strength to rural practice regardless of the type of work being done. Nonetheless, statutory obligations in some legislative areas such as child protection and mental health blur the lines between social care and social control (Harns and Connolly, 2008) and in rural areas, the high visibility of workers makes their work in these areas very complex.

Moreover, in small communities, professionals can be stigmatized for their roles in certain social interventions particularly related to family relationships, may feel a little 'on guard' and constantly in professional mode and thus continually check their social relations. Certainly, there is a degree of difference in this respect between those who are resident in a community and those who are visiting professionals, those more able to maintain strict boundaries.

This personal boundary and privacy issue is not limited to workers. Clients wishing to visit a social worker can be challenged if a service is too open. Gossip is a powerful form of information sharing in rural communities. For this reason many social workers have offices away from central areas, in shared locations with other health professionals or at the local hospital or health service and many have off-street parking to further protect clients.

A further critical personal barrier is the high visibility and lack of anonymity workers have in rural communities (Maidment, 2012). It is not unusual to see clients in the street, the supermarket, at social events and to feel that the lines between the personal and professional are constantly blurred. Many workers report their fear of violence, particularly in situations where they are dealing with violent perpetrators or child protection issues. Pugh (2007) terms these associations 'dual relationships' – the out of work hours connections with clients that he argues challenge our ethical understandings of good practice and confidentiality and reveal the difficulty of being a professional worker in a rural community, a position also recognized by First Nation and indigenous workers in Australia and Canada.

Recruiting and retaining social workers in rural areas is one of the main constraints on this field of practice. Identified reasons for this include the perceived professional and social isolation of rural work, a lack of professional opportunities, high workloads, expectations of on-call work, the temporary nature of some workplace contracts, poor employment supports, burnout, travel demands, and high visibility (Alston, 2009; Cheers et al., 2007). Professional isolation appears to be growing as areas decline, supervision arrangements are becoming more tenuous, and workers are working longer hours (Bowles, 2012; AIHW, 2009; Cheers et al., 2007). Despite the complexity and growing social issues in this field, rural health practice has been termed a 'professional nursery' because it attracts new graduates who stay for a couple of years before moving back to the city (Healy, 2004). The effects of the temporary and highly mobile workforce are that rural practice lacks not only a solid base of research but also long-term workers in rural practice can feel professionally isolated.

Rural Practice Opportunities

Nonetheless, there continues to be a rich vein of experienced social workers who are attracted to rural communities and

stay for lengthy periods. These long-term highly experienced workers provide a major, and often unheralded, contribution to the development of innovative social work practice. They have the capacity and creativity to try new programs, extend existing knowledge, and expand beyond traditional practice boundaries. It is here that rural social work practice finds its exciting and unique edge or what Maidment (2012: 17) describes as its "rich source of professional enlivenment." Perceived barriers can be turned into outstanding opportunities by these workers who know the strengths of the community. They can also challenge evident government neglect, expand community development opportunities, and drive innovative and critical change.

Where rural workers are sole practitioners or in small agencies, it is not unusual to find they have established extensive interagency groups to work collaboratively across agencies including the local police, ambulance and other health workers, high school representatives, community service organizations, and local neighborhood groups. Beddoe and Burley (2012) note that these multidisciplinary formal or informal networks provide professional enrichment as well as a way of addressing personal safety and isolation. These rich and diverse networks allow extensive interagency cooperation, empower the community, mobilize diverse groups, and often enable significant funding to be sourced for community development and innovative developments. Workers in these communities are not afraid to try new technologies, to develop professional opportunities, to expand the horizons of their community members, to activate governments and NGOs, and to bring their community's issues to the attention of policymakers. A good rural social worker can have a significant impact on the lives of those who live in the communities they serve and the opportunities available to them. These social workers have a deep commitment to their work, a strong desire to live in a rural area, extensive friendship and professional networks, high levels of autonomy, a delight in introducing innovative practice ideas, and a creative ability to balance work and family life (Alston, 2009; Cheers et al., 2007). There is no doubt these workers are among the leaders of our profession.

Improved Model of Rural Practice

While innovative practice is evident across rural areas, there are significant challenges that require an informed practice focus and framework. In this instance, the work of Maidment and Bay (2012: 222) in developing a set of principles that can shape a new understanding of rural practice is particularly useful. These include acknowledging the significance of place, governmentality, and the consequent way 'rural' is positioned in policy; positioning rural social work practice in a social justice framework; accepting interdisciplinarity; and developing comprehensive rural practice research to inform and develop this critical area of practice.

In previous work (Alston, 2004, 2005, 2007, 2009), the writer has argued for the identification of rural social work strategies and further development of a rural social work practice model. These can be summed up as follows. Rural social workers should:

- locate their work in the space between the community and external bodies;
- use a full range of social work skills;
- be strategic in using these skills;
- be inclusive;
- work across boundaries within and beyond the community;
- use existing formal and informal networks;
- work as a community animator (Cheers et al., 2007) mobilizing community strengths and shaping goals and activities;
- work with and support other human service workers;
- advocate for rural communities and people;
- advise governments and others on rural disadvantage and policy; and
- enable a voice for rural people (Alston, 2009).

Developing a more informed model of human service delivery is essential to improving the social supports available to rural communities. The withdrawal of governments from service delivery has left a hodge-podge, of disjointed, opportunistic, and often overlapping services with significant gaps in other areas. What is required is a new model of service infrastructure for rural areas that gives greater security to communities and to the workers who serve them.

This model should include a number of strategic elements including the following:

- rural policies based on social, as well as economic and environmental sustainability;
- regional social work hubs of skilled social workers available to provide supervision, professional development, and support for local social workers;
- the development of this hub-and-spoke model to provide a regional office base for local social workers to periodically work from, in order to gain collegial support and discuss strategies and cases;
- the employment of social workers at local government level to undertake community development and to oversee service infrastructure and development;
- the establishment of Social Inclusion Committees at local government level to assist and advise social workers;
- the establishment of a competitive rural fund similar to the European LEADER program that allows local government areas to bid for funding to develop socially inclusive practices and structures;
- extension of the use of existing infrastructure such as health services, high schools, and local government offices to maximize existing buildings for extended community capacity building activities such as education, IT support, and community activities; and
- advocacy and rural policy advice.

Conclusion

Rural social work practice is emerging as a leading field of innovative practice not least because of the factors shaping twenty-first century uncertainties. Climate variability,

globalization, growing uncertainties, and increasingly vulnerable populations are shaping rural areas as sites of increasing poverty and social insecurities. This article has outlined the factors that act to reinforce these insecurities – the nature of policies and practices that ignore and discount human rights and social impacts. This is fertile ground for social workers and there is increasing evidence of innovative social work practice in sites of slow rural decline or cataclysmic climate events.

Environmental incidents, globalization, and rural restructuring increasingly impact rural areas. Neoliberal policies and a focus on economic growth tend to blind policymakers to the social injustices inherent in a market-based approach. Social workers have a critical understanding of factors that shape social sustainability and are key professionals in rural areas.

Yet, rural social work is not without its challenges. Nonetheless, the opportunities presented by rural social work to be innovative and autonomous have enabled many social workers to find their home in rural areas, investing their professional energies in developing this critical area of practice. With more attention from policymakers and the profession, rural social work can be understood as one of the most critical areas of practice and an area of major significance to the advancement of human rights.

Abstract

Rural sociology is a field of applied sociological research and training that has historically focused on rural people and places. It has its intellectual origins and administrative home in the US Land-Grant System of colleges. Theoretical concerns historically centered on the implications of urbanization, modernization, and capitalist economic development. While the sociology of agriculture and environmental society represent major foci of investigation, rural sociology is much less parochial today than in the past, embracing substantive research themes, alternative methodologies, and policy issues that blur the boundaries with sociology. A new rural sociology emphasizes an emerging synthesis of research at the rural–urban interface.

Rural sociology is alternatively viewed as a subfield or specialty area in the discipline of sociology or as a discipline in its own right. This dualism reflects rural sociology's intellectual origins and history, its administratively ambiguous but changing place within the academy, and the recurring antipathy between rural sociologists and mainstream sociology that sometimes pivots on questions of the continuing relevance of rural issues, especially as urbanization continues apace. This intellectual and disciplinary separation also is rooted in different sources of funding (under the US Land-Grant System – or not), different emphases on theory and applied research and public engagement, and the physical separation and isolation of rural sociologists within America's public universities. But these historically distinguishing features of rural sociology are now rapidly breaking down as traditional sources of university funding (especially state and federal sources that in the past supported separate rural sociology departments, faculty appointments, and graduate student training) have dried up under the Land-Grant System. Today, rural and agricultural-related research (in the Agricultural Experiment Station) and public engagement and outreach (through the US Department of Agriculture's (USDA) Cooperative Extension Service) have focused on technical rather than on behavioral aspects of rural development and community change.

Rural sociology has traditionally been defined as the study of social organization and change that is characteristic of regions and places where populations are small, spatially dispersed, and economically underdeveloped (i.e., in rural areas, however defined). It has its origins in nineteenth-century intellectual thought, which often centered on debates over the implications for traditional rural social organization and farm life (e.g., cohesiveness or moral superiority) in the face of capitalist industrialization and modernization (Buttel, 2001). Rural sociology is rooted in the early work of Tonnies (*Gemeinschaft* and *Gesellschaft*) and the so-called rural–urban continuum (and the replacement of mechanical solidarity with organic solidarity). And, even today, research in rural sociology typically focuses on rural–urban differences, especially economic and social disparities in well-being.

The intellectual home of most self-identified rural sociologists is the Rural Sociological Society (RSS). Its flagship journal, *Rural Sociology*, was first published in 1937. It provides a forum for research on 'rural people, places, and problems.' The journal includes mostly empirical-based research studies related to rural economic development, environmental and demographic impacts, the structure of food and agricultural production, and rural–urban linkages, among other topics. But, increasingly, rural areas or communities simply serve as spatial containers for the comparative study of institutional change (e.g., families, health care, education, religion, and public policy). Some observers, in fact, claim that there is no 'rural' left in rural sociology (Friedland, 2002), that is, rural and urban people – at least in the United States and some Western industrial societies – are largely indistinguishable.

Indeed, the intellectual boundaries that sometimes separate rural sociology from sociology are rapidly changing. This reflects shifts in university priorities and funding. It also reflects demographic processes – aging and cohort replacement of its practitioners – within rural sociology itself. The heyday of rural sociology, if measured in resources and hiring, occurred in the 1970s. Over the past decade or two, rural sociology departments have shrunk in size (as has membership in the RSS) with the retirement of faculty and programmatic staff. In several cases (e.g., Washington State University or Texas A&M University), departments have been eliminated altogether and faculty have been dispersed or consolidated within other university programs (e.g., rural education and leadership). Other departments have redefined their research and teaching niche within the university and rural sociology. Some leading departments of rural sociology, for example, have renamed themselves, becoming Departments of Development Sociology (e.g., Cornell University), Community and Environmental Sociology (University of Wisconsin–Madison), or Community and Leadership Development (University of Kentucky) to better reflect their changing missions. In some Land-Grant Universities, sociology departments have regularly hired and trained rural sociologists, providing separate faculty lines both in colleges of agricultural science and other colleges, such as arts and sciences (e.g., North Carolina State University, Michigan State University, and Iowa State University). But the marriage of sociology and rural sociology has sometimes been an unhappy one, reflecting differences in theoretical perspectives, resources (e.g., 9- versus 12-month appointments), teaching loads, and missions (e.g., basic versus applied), which

inevitably led to differences in departmental expectations and rewards (e.g., tenure and promotion, and salary disparities). Other university sociology departments (such as Brigham Young University or the University of New Hampshire) have melded faculty with strong interests in rural sociology with those of other faculty who do not share their interests, but who nevertheless appreciate the value of rural-oriented applied work.

These changing institutional arrangements have fundamentally altered the practice of rural sociology over the past decade or two, blurring the boundaries that have historically separated its research, training, and outreach missions from mainstream sociology departments. For example, newly mined PhDs trained in rural sociology departments have increasingly found faculty appointments or research positions outside the Land-Grant System, in sociology departments and other programs in major research and teaching universities, in smaller state universities, and in private liberal arts colleges. The traditional topics of rural research and teaching – sociology of agriculture, food systems, environmental sociology, population studies, and the sociology of development – have been as a result not only dispersed more widely across higher education but also diluted by the research and training missions of their new homes outside the Land-Grant System.

Rural sociology, whether viewed as a sociological specialty or as a separate discipline (because of its institutional location within the University), has its origins within the US Land-Grant agricultural college system but owes its historical development (and the waxing and waning of scholarly interest and resources) to trends in agrarian politics and changing demography (e.g., urbanization and the decline in the farm population). To illustrate these points, this article is divided into three major sections. First, the author provides a short history of the origins of rural sociology, while highlighting its past and currents connections to mainstream sociological theory and research. Second, the author highlights recent changes in the major substantive research interests and empirical approaches in rural sociology since the boom period of the 1970s. And, third, the author describes a 'new' rural sociology that acknowledges the increasing interconnections between rural and urban scholarship at the rural–urban interface in a rapidly globalizing and interconnected world (Lichter and Brown, 2011). Rural sociology arguably is being mainstreamed within the broader discipline of Sociology and expanding outside the United States, especially in European countries. Rural sociology's institutional and intellectual home is currently in flux, but reemerging as a significant subfield or specialty areas within sociology itself, a place where it started nearly 100 years ago.

Institutional and Intellectual Origins of Rural Sociology

Rural sociology is a product of the US Land-Grant System, as established by the Morrill Land-Grant College Act of 1862. In 1890, this legislation was extended to include traditionally black institutions in southern states (e.g., Alcorn State University, Florida A&M University, Tuskegee University, and Prairie View University), which are still sometimes called '1890s schools.' Each state established agricultural experiment stations, usually in a designated Land-Grant University, that worked collaboratively with the USDA in Washington, DC, to provide empirically based, scientific, and practical agricultural information (e.g., hybrid seeding, plant rotation, irrigation systems, and social erosion) for rural farmers and ranchers – to make their farm operations more cost-effective and productive. In 1887, the Hatch Act forged a new federal–state partnership for agricultural research. This was followed in 1914 by the Smith–Lever Act, which established the cooperative extension service. The idea, which started at the University of Wisconsin–Madison (the 'Wisconsin idea'), was to extend scientific knowledge (and in some cases, 'culture') to the countryside, and rural sociologists participated through research supported by agricultural experiment stations. To promote economic development, extension rural sociologists cooperated in outreach activities with state and local organizations, public officials, and policy makers, and with their counterparts in the USDA.

In 1908, President Theodore Roosevelt appointed a Presidential Commission on Country Life. The County Life Commission Report, which was published in 1909, made the case that economic development and modernization were required to improve the conditions of rural people and places. According to Buttel (2001: p. 13430), the Commission recommended "the harnessing of the social sciences, particularly agricultural economics and rural sociology, to support the technological modernizationist vision for rural America." The Commission's report was a major boon to rural-related social sciences in the Land-Grant system.

Indeed, some of the early and most influential work by rural sociologists focused on the adoption-diffusion process of innovative farming practices, as pioneered by Everett Rodgers and colleagues and students at Iowa State University (Fliegel, 1993). And, even today, many rural sociologists in the Land-Grant System hold part-time experiment station and/or extension appointments rather than teaching appointments. Over the last decade or two, however, appointments of this type have declined significantly. Faculty members in rural sociology departments today nevertheless continue to be heavily engaged in applied sociological research – in public sociology – that serves state and community stakeholders. But unlike the past, their work has become less parochial, focusing less directly on state or community issues and more on national and international concerns (e.g., economic development, environmental degradation, or rural depopulation). The days of writing descriptive experiment station bulletins that mostly focused on state or local issues is over, replaced by a new emphasis on basic and applied research, teaching, and service that meets the usual standards of scholarly productivity used by their academic counterparts in sociology departments on the other side of campus or at other institutions.

This represents a return to the past, at least in some ways. In the beginning, the field's early practitioners typically were identified as rural sociology section members under the organizational umbrella of the American Sociological Society (now the American Sociological Association (ASA)). But the rural sociology section broke off from ASA in 1937 to form the RSS. Since then, membership in the RSS reached its peak of 1101 in 1997 (Krannich, 2008). Today, RSS membership is down to

about 600 members, but holding steady over the past several years. Membership declines have understandably been cause for alarm and some self-deprecation (Beaulieu, 2005; Krannich, 2008; Singelmann, 1996), but such pessimism is warranted only if recent institutional shifts are considered in isolation of other measures of vitality and impact. For example, declines in RSS membership partly reflect healthy organizational shifts in mainstream sociology, such as the establishment of highly specialized ASA sections in development sociology or environmental sociology, as well as new professional associations that have attracted rural sociologists but sometimes siphoned membership from RSS. Many rural sociologists, including RSS members, are heavily involved today with the Community Development Society (which publishes *Journal of the Community Development Society*), International Association for Society and Natural Resources (*Society & Natural Resources: An International Journal*), and the Agriculture, Food, and Human Values Society (*Agriculture and Human Values*).

Equally important to rural sociology, if viewed as a subfield of sociology, has been the growth of interest in rural sociology and rural studies in Europe (Cloke et al., 2006) and throughout the international scholarly community of sociologists. The European Society for Rural Sociology was formed in 1957, and began publishing *Sociologia Ruralis* in 1960. The International Rural Sociological Association was established in 1976, which merged the activities of three regional rural sociology societies. A 'World Congress of Rural Sociology' has been held every 4 years since 1964 (when it was first held in Dijon, France). The XIV World Congress of Rural Sociology is scheduled for Toronto, Canada, in 2016. Buttressing international interest of rural sociology and rural social science, the multidisciplinary *Journal of Rural Studies* was first published in 1985. The paradox today is that growing interest in the subject matter, theoretical perspectives, and empirical approaches of rural sociologists has perhaps never been greater, yet the institutional support for rural sociology in the academy has undoubtedly waned, especially in the United States.

The point here is straightforward: The intellectual health and vitality of rural sociology cannot be measured simply by the number and size of rural sociology departments, by membership in the RSS, or by changes in the number of North American practitioners. Today, the growing scholarly integration between rural and (urban) sociology harkens back to an earlier period of history of sociological thought when some of sociology's most distinguished practitioners had their intellectual roots in rural sociology. Just a few examples suffice to make the point. Rural sociological research was spearheaded in the 1910s by Charles J. Galpin through his rural life studies at the University of Wisconsin. The program was housed in the Department of the Agricultural Economics, and a separate Rural Sociology department was first established in 1930 by J.H. Kolb. Franklin Giddings helped establish a major course of study in rural sociology at Columbia University in the 1920s. Pitirim Sorokin and Charles Zimmerman published *Principles of Rural-Urban Sociology* in 1929. More recently, Otis Dudley Duncan started his career in rural sociology in the 1950s at Pennsylvania State University. Another iconic figure in social stratification and mobility, William Sewell, began his career in the Department of Rural Sociology at the University of Wisconsin–Madison. Even more recently, a prominent Princeton sociologist, Robert Wuthnow, has published *Small-Town America: Finding Community, Shaping the Future* (2013). The point here is that rural sociology has not only a proud history, but also an optimistic future if the spotlight is placed less on organizational change and more on the growing interest in the subject matter itself and on newly formed connections to mainstream sociology and to the broader social scientific community.

Research Themes in Rural Sociology

To understand rural sociology today requires separating its historical origins and current institutional arrangements from its scholarly content (i.e., what rural sociologists actually do). A recent review (Buttel, 2001) claims that rural sociology is divided into six major branches: rural population, rural community, natural resources and environment, agriculture, sociology of international rural development, and sociology of agricultural science and technology. But this assessment arguably gives too much internal coherence to a field that is in flux. It may also narrow the scope of the field, while creating artificial and sometimes unnecessary boundaries between substantive areas in rural sociology. Moreover, most of the usual fields of endeavor that typically define mainstream sociology are also represented in rural sociology. And some newly emerging research themes in rural sociology, such as immigration, health, and agrifood systems, reflect ongoing social, economic, and political changes that now characterize the rural landscape, both in the United States and in other developed and developing societies.

One way to define rural sociology is by the way rural sociologists define themselves – by what they study and write about. Every 10 years or so, the RSS takes stock of the field, providing its "readers a forward-looking, policy-relevant state of the art understanding of rural people and places and the challenges they face" (Bailey et al., 2014). The latest volume, published in 2014, is the fourth in the series, beginning with Donald Dillman and Darryl Hobbs' (1982) *Rural Society in the U.S.: Issues for the 1980s*. This inaugural volume was followed by state-of-field volumes in 1991 by Cornelia Flora and James Christenson (*Rural Policies for the 1990s*) and again in 2003 by David Brown and Louis Swanson (*Challenges for Rural America in the Twenty-First Century*). The most recent volume, coedited by Connor Bailey, Leif Jensen, and Elizabeth Ransom, is entitled *Rural America in a Globalizing World: Problems and Prospects for the 2010s*. The title itself is clearly indicative of rural sociology's expanding research concerns about the impact of globalization and rural America's growing interconnections with urban America and the rest of the world. But it is also distinctive in other ways that reflect changes in rural sociology, including for the first time a coeditor located outside the Land-Grant System and a woman (reflecting the gender transformation of the field over the past decade or two).

As a document of record, *Rural America in a Globalizing World* is divided into five major sections that fairly define the rural sociology: (1) changing structure of agriculture, (2) natural resources and environment, (3) population change in rural North America, (4) diversity in rural America, and (5) rural economies, community, and quality of life. The chapters on agriculture focus primarily on the agrifood system, on the bifurcation of the America (i.e., corporate and hobby/organic/specialty farming), land ownership and consolidation,

agricultural workers and changing technology, food safety, animal welfare (e.g., humane slaughtering practices), and agrifood social movements (e.g., organic farming, farmer's markets, and hormone-free meat). The guiding perspective today focuses on the changing structure of agriculture and food systems, the movement from a system based on family farms to one that is highly industrialized and highly interconnected to many aspects of the global economy (Lobao and Meyer, 2001). North American agriculture has moved from a system based on family farms to global commodity systems dominated by multinational corporations. Neoliberalism, the deregulation of financial markets, free trade and global markets, and the consolidation of corporate power in the food industry have had profound impacts on rural workers and communities (Bonanno, 2014). Today, the sociology of agriculture may be the largest research area in rural sociology, and it has expanded in scope and influence over the past two decades.

Agriculture arguably also is an area unique to the field; there are few sociologists in mainstream sociology departments who study the changing structure of agriculture. But this is likely to change as the implications of food systems for traditional areas of sociological and economic study are made clear in the future. At the same time, rural agricultural issues – farming and food systems – is related to many significant dimensions of the United States and global economy that have attracted broad sociological and demographic interest. For example, changes in meat production, processing, and distribution have impacted America's small towns, especially in the agricultural Midwest and Southeast. The demand for cheap labor has attracted new immigrant workers and their families; Hispanics accounted for more than half of all growth in nonmetropolitan counties over the period 2000–10. New immigration has dramatically changed the ethnic mix of rural communities, patterns of economic and political incorporation, and many rural institutions, including education, religion, and family (Lichter, 2012). In some cases, the in-migration of Hispanic immigrants has been a lifeline to dying small towns. Figuratively, many mainstream sociologists have followed new immigrants to the rural countryside (Massey, 2008) and blurred the disciplinary and intellectual boundaries that have sometimes separated sociology and rural sociology.

With its historical emphasis on natural resources (e.g., wildlife, forests, minerals, water, and soil), environmental sociology has been a fundamental topic of intellectual pursuit among rural sociologists (Fortmann et al., 2014). Interest has now expanded with growing concerns about the societal implications of climate change, environmental degradation, and sustainability, both in the United States and elsewhere (Dunlap, 2010; Freudenburg, 2006). This is a big topic today of immense importance for sociological theory and research (e.g., social movements, inequality, and social disorganization) and public policy. It also merges interests with the natural and biological sciences. Rural America, for example, comprises over 70% of America's land area, a fact that requires good stewardship. New demands for cheap supplies of renewal energy also have spurred rural-oriented sociologists to become increasingly interested in 'fracking' for natural gas – its impacts on water quality, community disorganization and crime, traffic congestion and housing, and population and employment growth. Innovations in biofuels (e.g., ethanol from corn or other plants) and electricity from wind turbines also have potentially large economic and social implications for sparsely settled rural areas. Financialization, especially in the form of commodification (e.g., of nature), marketization (e.g., international 'land grabs'), and privatization (e.g., of government land) is often expressed in conservation policy (e.g., cap and trade) (Fortmann et al., 2014). In some cases, rural areas also have become 'dumping grounds' for urban refuse (e.g., garbage) and hazardous wastes that raise concerns about the health and well-being of rural people and communities.

This work often follows in the tradition of sociological work in resource-dependent communities and the economic and environmental exploitation of outside corporate interests, which is sometimes typified in poor coal-producing areas in central Appalachia and timber-dependent communities in the Pacific Northwest and elsewhere. The work also is rooted theoretically in The Chicago School of Sociology, which used Chicago neighborhoods in the early 1900s as naturally occurring laboratories for studying the consequences of urbanization and growing ethnic diversity for community life (e.g., social disorganization and anomie). Rapidly changing rural communities arguably now occupy this place in America's social history.

The continuing consolidation of agricultural production, rural industrial restructuring, and economic competition from overseas markets have contributed to slow growth and even population decline in many parts of rural America. Indeed, for the first time ever, nonmetropolitan counties – in the aggregate – experienced depopulation (over 2010–12). The long-term declines in rural population have provided a continuing source of urban growth, usually in the form of new in-migrants of reproductive ages. Rural out-migration and population decline has always been a major topic of research interest among rural sociologists, a topic usually framed and informed by Amos Hawley's Human Ecology perspective (Fuguitt et al., 1989). More recent research has given greater agency to rural communities (by embracing a 'political economy of places'). Population trends are linked to economic development, community fiscal viability, and health and economic well-being. In many cases, chronic out-migration – the loss of rural America's 'best and brightest' – has sapped the lifeblood from rural agricultural and resource-dependent areas. Moreover, a large second-order effect of chronic rural out-migration has been natural decrease – the excess of deaths over births. Rural populations have aged rapidly in combination with below-replacement fertility, both in the United States and in Europe. Most nonmetropolitan counties today are experiencing natural decrease over the 2000–10 period. Many parts of rural Europe (e.g., southwest Germany and the northern parts of The Netherlands and Northern Ireland) face similar problems of population aging, out-migration, and depopulation.

These population shifts have occurred unevenly across regions of the United States and Europe, and are experienced differently among different demographic segments (e.g., children, the elderly, and minorities) of the population (Kulcsar and Curtis, 2012). Uneven demographic change has raised the specter of increasing spatial inequality (Lobao et al., 2007), as some rural areas have emerged as economic winners (e.g., rural and recreational amenity areas), while others have languished (e.g., rural parts of Central Appalachia). Growing

income and wealth inequality – from one place or region to another – reflects, at least in part, growing economic inequality more generally in America. A new kind of geographic economic balkanization has attracted the scholarly interest of sociologists (who tend to focus on concentrated neighborhood poverty and economic segregation) and rural-oriented sociologists (whose work typically has centered on 'places left behind' by economic restructuring and globalism, such as Appalachia, the Delta, and isolated areas in the rural South).

Rural communities are not homogenous – economically, politically, or culturally. Increasingly, rural communities provide convenient, accessible, and relatively inexpensive venues for cutting-edge comparative research, using quantitative (based on secondary or primary survey data), qualitative, or mixed-methods approaches. What is sometimes sacrificed in representativeness is more than made up with depth and new sociological insights. A few examples suffice to illustrate the point.

For example, in *Hollowing Out the Middle*, Patrick Carr and Maria Kefalas (2009) spent several months living in a small town in Iowa, where they sought to better understand why some high school graduates left the community (labeled 'achievers') and others stayed, and the role that community and school investments played in reinforcing out-migration and contributing to their own demise. This community-based ethnography primarily focused on the rural 'brain drain' but provided more general sociological and policy lessons for all communities, not just small towns. A central point was that class divisions cause some communities to invest most heavily in young people who they prepare to leave, rather than in those students who are most likely to stay and contribute positively to civic life. Another recent book, by David Brown and Nina Glasgow (2008), used a mixed-method approach to examine retirement migration. *Rural Retirement Migration* is based on national level secondary data analysis, survey data of older persons (in-migrants and longer term residents) in 14 counties with high rates of elderly in-migration, and in-depth studies of four retirement destinations. The authors demonstrated the large and diverse economic and civic contributions of older in-migrants – who often come from big cities – and how they lead productive lives in older age, but also represent 'gray gold' in some communities. Again, this is a volume of broad sociological interest; rural communities provide a useful geographic container for studying successful aging in America. Finally, Jennifer Sherman's *Those Who Work, Those Who Don't: Poverty, Morality, and Family in Rural America* (2009) provided a cultural sociology of small town life (in the America Northwest). She focused not only on families experiencing economic hardship, but also on how choices were affected by economic constraints and shaped by cultural and moral understandings that organize social life in cohesive communities. Here, rural communities illustrate fundamental sociological lessons about how low-income mothers adapt to economic exigencies and make ends meet.

Rural America today arguably is on the frontline of social changes that have broad sociological and demographic significance. Its diversity also has advantages for comparative studies of social organization and processes – race relations, politics, social stratification, institutional change (e.g., schools), cultural clashes, and development. For example, rural areas are sometimes viewed as safe havens for traditional families and social ties. But the evidence suggests otherwise (Smith and Tickamyer, 2011). Rural families today look remarkably similar to urban families – in patterns of nonmarital fertility, cohabitation, divorce, single-parent families, and children exposed to diverse living arrangements. Family changes have been unusually rapid in rural communities. Population aging has been rapid in many rural areas, owing in large part to chronic out-migration, low fertility, and 'aging in place.' Rural America has become a new destination for Hispanics – both natives and foreign born. Issues of diversity and racial relations are rapidly being transformed in many new 'majority–minority' rural communities (Lichter, 2012). At the same time, black poverty and racial inequality remain extreme in the rural South, a legacy of slavery, the plantation economy, and its racially oppressive aftermath (Green, 2014). America's Indian reservations also highlight issues of spatial and racial inequality, as well as illustrate America's incorrigible geography of exclusion. Diversity is also illustrated by a new geography of sexuality, where some small towns have become home for sexual minorities (especially lesbians) or have emerged as places of recreation (e.g., Wellfleet, MA, or Key West, FL).

A New Rural Sociology?

In his 1983 paper in the *Annual Review of Sociology*, Howard Newby (1983) called for a 'new' rural sociology that emphasized agriculture as the intellectual lynchpin, and also provided a critique of rural sociology and, by extension, its practitioners in the Land-Grant System, who are sometimes painted as apologists for 'big agriculture.' Indeed, the aforementioned rural realities of the last half century (and more) ushered in various critical theories that sometimes framed the new rural sociology. They drew heavily from neo-Marxism and also from neo-Weberianism perspectives, the peasant studies literature, and critical theories drawn from hermeneutics and related traditions (Buttel, 2001). They represented a critique of modernization (as exemplified in diffusion studies and rural demography) within rural sociology, of quantitative research and training, and of the Land-Grant missions as defined by experiment station research and cooperative extension.
